REPORT DOCUMENTATION PAGE				Form Approved OMB No. 0704-0188	
Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing this collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number. PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ADDRESS.

Ser: 21

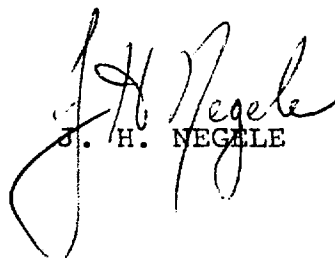

16 JAN 1970

From: Commanding Officer, U. S. Fleet Weather Central/Joint
Typhoon Warning Center, Guam
To: Chief of Naval Operations
Via: Commander, Naval Weather Service Command

Subj: Annual Typhoon Report, 1969; submission of

Ref: (a) OPNAV Instruction 3140.17E of 29 Oct 65
(b) SECNAV Instruction 5600.16 of 2 Nov 60

1. The Annual Typhoon Report, 1969, is submitted herewith in accordance with reference (a).
2. During calendar year 1969, 13 typhoons, 6 tropical storms and 4 depressions were detected in the Western North Pacific from the International Date Line to the Malay Peninsula. A total of 430 warnings were issued during the 108 calendar days of "warning status" for the Joint Typhoon Warning Center, Guam.
3. Reference (a) directs Fleet Weather Central Pearl Harbor and Fleet Weather Central Alameda to forward annual summaries of tropical cyclones in their respective areas to this command for inclusion in Annual Typhoon Reports. Fleet Weather Central Pearl issued no tropical cyclone warnings during 1969. Fleet Weather Central Alameda was in warning status 67 days during 1969 and issued a total of 219 warnings on 4 hurricanes, 6 tropical storms and 5 tropical depressions.
4. This report has been reviewed in accordance with reference (b).

FOREWARD

This report is published annually and summarizes Western North Pacific Tropical Cyclones. Annex A summarizes Tropical Cyclones from 180 degrees eastward to the North American Coast.

When directed by CINCPAC in May 1959, CINCPACFLT redesignated Fleet Weather Central Guam as Fleet Weather Central/Joint Typhoon Warning Center (FWC/JTWC), Guam with the following responsibilities:

1. To provide warnings to U. S. Government agencies for all tropical cyclones north of the equator and west of 180 degrees longitude to the coast of Asia and Malay Peninsula.
2. To determine tropical cyclone reconnaissance requirements and assign priorities.
3. To conduct investigative and post-analysis programs including preparation of the Annual Typhoon Report.
4. To conduct tropical cyclone forecasting and detection research as practicable.

Air Force Asian Weather Central at Fuchu, coordinating with U. S. Navy Fleet Weather Facility Yokosuka was designated as alternate JTWC in case of failure of FWC/JTWC Guam.

The JTWC is an integral section of FWC/JTWC Guam and is authorized to be manned by three Air Force and three Navy officers and five enlisted men from each service. The senior Air Force Officer is designated as Director, JTWC.

The Western Pacific Tropical Cyclone Warning System consists of the Joint Typhoon Warning Center (JTWC), the U. S. Air Force 54th Weather Reconnaissance Squadron stationed at Andersen Air Force Base, Guam and U. S. Navy Airborne Early Warning Squadron One (VW-1) stationed at Naval Air Station, Agana, Guam.

The Joint Hurricane Warning Center in Hawaii, a coordinated agency composed of the U. S. Weather Bureau, Honolulu, the Air Force Central Pacific Forecast Center, and Fleet Weather Central Pearl Harbor, is responsible for tropical cyclone surveillance and issuance of warnings in the Central North Pacific area between 180 degrees and 140 degrees west.

U. S. Navy Fleet Weather Central, Alameda, California, is responsible for issuance of warnings from 140 degrees west longitude to the North American Coast.

CHAPTER I

OPERATIONAL PROCEDURES

A. GENERAL

Services provided by the Joint Typhoon Warning Center (JTWC) include forecasts of tropical cyclone formation, intensification, direction of motion, speed of movement, wind intensity and changes in the size and intensity of the cyclone. The primary product of JTWC providing these services is the tropical cyclone warning issued in 1969 at 05Z, 11Z, 17Z and 23Z whenever tropical cyclones existed in the JTWC area.

FWC Guam provides computer and analysis support for JTWC.

Communications services for JTWC are provided by the Fleet Weather Central Nimitz Hill Division of Naval Communications Station, Guam.

B. ANALYSES AND DATA SOURCES

1. FWC ANALYSES:

a. Surface polar projection isobaric; 0000Z, 0600Z, 1200Z and 1800Z.

b. Surface mercator projection isobaric; 0600Z and 1800Z.

c. Surface micro-analysis of South China Sea region; 0000Z, 0600Z, 1200Z and 1800Z.

d. Sea surface temperature charts; daily.

e. Checkerboards (Stidd Diagrams) of selected tropical stations.

f. Time cross sections of selected tropical stations.

2. JTWC ANALYSES:

a. Sectional surface isobaric charts; hourly and 3 hourly as required.

b. Reconnaissance data.

c. 700 mb mercator projection contours; 0000Z and 1200Z.

d. 500 mb mercator projection contours; 0000Z and 1200Z.

e. 300 mb mercator projection contours; 0000Z and 1200Z.

f. Stidd diagrams of selected stations in the van of an approaching storm.

3. SATELLITE DATA:

The quality and quantity of satellite data available in 1969 was greater than ever before. ESSA 6 (later replaced by ESSA 8) and NIMBUS 3 provided local morning direct readout pictures. Nimbus 3 provided infrared direct readout pictures at night. Local afternoon ATS satellite pictures were available as a rectified digitized mosaic chart after an eight hour delay for processing.

4. RADAR:

Installation of weather radar at FWC Guam was completed in time for the 1969 typhoon season, but did not see much action.

5. COMPUTER PRODUCTS, 0000Z AND 1200Z:

a. Hemispheric analyses and barotropic prognoses for 1000 mb, 700 mb, 500 mb, 300 mb, and 200 mb.

b. Decomposition fields of the 500 mb (SD, SR and SL) analyses and prognoses. The SD, SR, and SL fields correspond to small scale disturbances, mean flow and long wave pattern respectively.

c. Computer analysis of tropical streamlines for the 700 mb, 500 mb, 400 mb, 300 mb, 250 mb, and 200 mb levels from FWC Pearl fields were used in 1969.

d. The HATRACK typhoon steering program based on SR prognostic fields was used on an operational time basis as a forecast aid.

e. The TYRACK typhoon steering program was operationally used during the 1969 season. This program utilizes the FWC Pearl tropical streamline fields for determining forecast movement.

f. Divergence charts based on FWC Pearl streamline fields were produced for evaluation beginning about 20 July. A preliminary report is included in Chapter III.

C. FORECAST AIDS

1. CLIMATOLOGY:

The following climatological publications were utilized:

a. Tropical Cyclones in the Western Pacific and China Sea Area (Royal Observatory, Hong Kong), covering 70 years of typhoon tracks.

b. Climatological Aid to Forecasting Typhoon Movement (1st Weather Wing).

c. Climatological 24-Hour Typhoon Movement (McCabe, J. T., 1961).

d. Western Pacific Typhoon Tracks, 1950-1959 (FWC/JTWC).

e. Far East Climate Atlas (First Weather Wing February 1963).

f. Annual Typhoon Report, 1968 (FWC/JTWC), covering tracks for 1959 - 1968.

2. PERSISTENCE:

Extrapolation of storm movement using average speed and mean direction was the most reliable method for 12 to 24 hour forecasts.

3. COMPUTER PRODUCTS:

a. The HATRACK typhoon steering program was run on the FWC Guam computer on an operational basis during 1969. Steering forecasts were made using the decomposition mean flow fields (SR) of the 700 mb, and 500 mb levels for prognostic fields through 72 hours. Empirical modification based on apparent error in earlier forecasts was used to obtain improved forecast positions.

b. TYRACK computer forecast steering from the 700 mb, 500 mb, 400 mb, 300 mb, mean 700/500 mb and mean 700/500/400/300 mb levels were used during 1969.

4. OBJECTIVE TECHNIQUES

During 1969 the following individual objective forecasting methods were employed:

a. ARAKAWA - surface pressure grid model.

b. HATRACK - based on 700 mb SR prognosis.

c. HATRACK - modified from 700 mb SR prognosis for 12 hour error. (for 24 hour forecasts)

d. HATRACK - modified from 700 mb SR prognosis for 24 hour error. (for 48 hour forecasts)

e. HATRACK - based on 500 mb SR prognosis.

f. TYRACK - based on program-selected best steering level from Pearl tropical fields.

Evaluation of these techniques is contained in Chapter III.

D. FORECASTING PROCEDURES:

An initial track based on climatology and extrapolation is developed for a 3 to 4 day period. The track is modified by considering the existing and forecast upper air patterns, numerical steering forecasts and the ARAKAWA objective method.

Subsequent forecasts become "educated" by longer period averaging of extrapolation error in speed and direction and through modification of computer forecasts to compensate for errors observed in earlier computer forecasts. A combination of extrapolation and climatology is the starting point for each forecast, with mesoscale analysis of the 700, 500 and 300 mb charts and the ARAKAWA objective forecast model used to modify or reinforce the extrapolation forecast. Position of tropical cyclones with respect to the 700 mb high center and ridge to the north and the 700 mb trough or break in the ridge to the west are the primary keys to 24 hour forecasting of recurvature or speed changes. The 200 mb level has been used to anticipate changes in intensity through assumptions of divergence in the southeast quadrant and convergence in the southwest quadrant of anticyclones. Tropical cyclones approaching a 200 mb anticyclone from the southeast are forecasted to intensify and those emerging from the west side of a 200 mb anticyclone are normally forecasted to weaken.

Extended range forecasting is based on extrapolation of the 24 hour track with reversion toward climatology and modified by SR and SL 500 mb forecast contours.

The resulting official forecast is an integration of both objective and subjective techniques with persistence in speed and direction the weighted favorite for short term forecasts.

E. WARNINGS:

Tropical cyclone warnings are numbered consecutively without regard for upgrading or downgrading of the storm between intensity stages. If warnings are discontinued and the storm again intensifies, warnings are numbered consecutively from the last warning issued. Amended or corrected warnings are given the same number as the warnings they modify. Forecast positions are issued as follows:

Tropical depressions	24 hr
Tropical storms	12, 24, and 48 hr (72 hr at 05Z and 17Z only)
Typhoons	12, 24, and 48 hr (72 hr at 05Z and 17Z only)

Forecast periods are stated with respect to warning time. Thus a 24 hour forecast verifies 26 hours after the aircraft fix data, 29 hours after the latest surface synoptic chart and 29 to 35 hours after the latest upper air charts.

Warning forecast positions are verified against the corresponding post analysis "best track" positions. A summary of results from 1969 is presented in Chapter III.

F. PROGNOSTIC REASONING MESSAGE:

Whenever warnings are being issued, an amplifying message is issued at 06Z and 18Z. This prognostic reasoning message is intended to provide meteorological units ashore and afloat with technical and non-technical reasoning appropriate to the behavior of current storms and the logic of the latest JTWC warnings.

G. TROPICAL WEATHER SUMMARY:

This message is issued daily from May through December and otherwise when significant tropical cyclogenesis is forecasted or observed. It is issued at 0600Z and combined with the prognostic reasoning message when warnings are being issued. It describes the location, intensity and likelihood of development of all tropical low pressure areas and significant cloud "blobs" detected by satellite.

CHAPTER II

RECONNAISSANCE

A. GENERAL

Land station and ship reports continue to be scarce in areas of tropical cyclone formation. The tropical cyclone warning system depends upon aircraft reconnaissance data to fix the location and strength of tropical cyclones. Only on rare occasions are land radar fixes or sequential reports available to compare with reconnaissance data. Increased satellite coverage during 1969 proved to be an invaluable aid in scheduling aircraft reconnaissance to achieve maximum effectiveness. Interpretation of storm intensity and center location from satellite pictures only is presently not sufficiently reliable for operational use. Continuous surveillance of tropical cyclones is of the utmost importance as illustrated by the explosive deepening of typhoon Kathy on November 6 from a system requiring great skill and persistence to locate in the afternoon to a nighttime reconnaissance indication of 60 knots only 12 hours later.

Four fixes per day were scheduled on all tropical cyclones following the initial fix which was normally coordinated with the earliest availability of reconnaissance aircraft on the scene. As a general rule VW-1 made fixes at 0900Z and 1500Z at low and intermediate levels and 54WRS made fixes at 2100Z and 0300Z at intermediate (700 mb) level. High level (500 mb) fixes were made on storms in the vicinity of higher terrain. Most storms were taken into warning on the basis of daylight investigative flight data.

B. RECONNAISSANCE RESPONSIBILITY

Squadrons responding to the reconnaissance requirements of JTWC through the TCRC in 1969 were U. S. Air Force 54th Weather Reconnaissance Squadron (54WRS) flying WC-130 aircraft from Andersen Air Force Base, Guam and the U. S. Navy Airborne Early Warning Squadron ONE (VW-1) flying WC 121N aircraft from the Naval Air Station, Agana, Guam.

C. EVALUATION OF DATA

Eye data from tropical cyclones is provided by low level penetration, intermediate level penetration or radar fixes from outside the center. Penetration data provides the best quality data including dropsonde soundings, minimum 700 mb height and sea level pressure, maximum observed wind (estimated), shape and character of the eye and feeder band information. The primary center of the cyclone is based on the location of minimum pressure at the surface, a parameter best obtained by low level penetration, however the nearly vertical structure of most tropical cyclones promises only slight loss of accuracy on intermediate penetration fixes. Radar fixes made outside the center introduce an attenuation and radar accuracy error not present in penetration fixes. Radar fixes are also based on the radar center rather than the pressure center of the storm. Not infrequently reports of centers determined independently by

wind, clouds, pressure and temperature will vary by 10 miles or more. The eye report contains a subjective estimate of fix accuracy which must also be taken into account in the determination of the storm location at warning time. A final factor in this determination is the forecasters ability to accurately forecast the direction and speed of movement of the storm. On a statistical basis this error rate is 4 to 5 miles per hour of forecast time. During 1969 the mean difference between the post analysis warning position and the published operational warning position was 20.7 N.M. Since the mean time difference from fix to warning time is two hours the forecast error contribution is 9 to 10 miles leaving a residual value of 11 N.M. attributed to the mean accuracy of reconnaissance fixes.

Short term variability in the actual cyclone track and the mean amount of "smoothing" incorporated in the best track analysis are subjective factors included within the 11 N.M. accuracy accorded reconnaissance fixes in operation use.

Maximum differences between warning positions and best track positions resulted when reconnaissance was not continuously maintained, when the developing storm has an indistinct and shifting center or when fix positions used for the warning position fell well outside the past season best track analysis.

D. COMMUNICATIONS

The primary means of communication between JTWC and reconnaissance aircraft was voice single sideband through Andersen Airways (AIE 2) serving as the primary air to ground station for both 54WRS and VW-1 weather missions. Secondary air to ground stations were Clark AFB, Fuchu Airways and Kadena Airways. When secondary ground stations were used eye data was passed to JTWC via the Joint Overseas Switch (JOSS). Eye data messages received by Andersen Airways were simultaneously received at JTWC by direct phone patch. A hard copy backup message was transmitted from Andersen over local teletype circuit SDE 9.

Average delay time from time of fix to receipt in JTWC by phone patch was 20 minutes including message preparation time in the aircraft and time to copy the message in JTWC. Maximum delay time by phone patch was 1 hour 21 minutes and minimum delay just a few minutes. Direct communications with reconnaissance aircraft permitted direction of aircraft on synoptic missions into areas of suspicion appearing on satellite.

E. SUMMARY OF RECONNAISSANCE SUPPORT

A reconnaissance fix accreditation system was devised in 1965 in an effort to establish an objective evaluation of reconnaissance effectiveness. The system has been in use with minor modifications since that time.

Fix times are scheduled as near as possible to warning time to still permit receipt of the data for consideration by JTWC

forecasters before release of the official warning. Prior to 1967 it was necessary to schedule fixes three hours before warning time. Improved communications in 1967 made it possible to schedule fixes only two hours before warning time.

AIRCRAFT RECONNAISSANCE DATA
(NUMBER OF FIXES AND INVESTIGATIONS)

<u>1961</u>	<u>1962</u>	<u>1963</u>	<u>1964</u>	<u>1965</u>	<u>1966</u>	<u>1967</u>	<u>1968</u>	<u>1969</u>
350	496	465	772	666	674	845	807	468*

*76 preliminary or intermediate (No Credit) fixes not included.

In addition there were 203 synoptic tracks flown in 1969.

TABLE 2-1

DELAY IN RECEIPT OF RECONNAISSANCE FIX DATA FOR 1969

<u>METHOD</u>	<u>NUMBER OF CASES*</u>	<u>MAX DELAY TIME</u>	<u>MIN DELAY TIME</u>	<u>AVG DELAY TIME</u>
PHONE PATCH	402	1 HR 21 MIN	0 HR 01 MIN	0 HR 20 MIN

*Since 1967, fixes scheduled 2 hours prior to warning time vice 3 hours prior to warning time during previous years.

TABLE 2-3

DEFINITION OF FIX CREDITS AND EVALUATION OF
TIMELINESS OF RECONNAISSANCE FOR 1969

<u>CLASS</u>	<u>DEFINITION</u>		<u>1969</u>
1	FULL CREDIT	From 1 hour before to 1/2 hour after levied time.	360
2	FULL CREDIT	Aircraft in assigned area within 1 hour before to 1/2 hour after levied time but unable to locate a center.	14
3	EARLY/LATE	Center located 1 to 1 1/2 hours before or 1/2 to 2 hours after levied time.	10
4	VERY EARLY/ VERY LATE	Greater than 1 1/2 hours before or more than 2 hours after levied time.	3
5	ATTEMPTED BUT MISSED FIX	Recon provided some useful peripheral data but no fix was made. Reasons may include clearance problems, mechanical trouble, low fuel, etc.	0
6	MISSED FIX	Missed fixes not falling into any category above.	6
7	FULL CREDIT	Fix made on investigative flight or synoptic track.	32
8	FULL CREDIT	Investigative flight, no fix made.	49
9	NO CREDIT	Preliminary or intermediate fix made between scheduled fixes.	76

CHAPTER III

JOINT TYPHOON WARNING CENTER STUDIES

A. An Analysis of Tropical Cyclone Wind Velocity Forecasting Accuracy.

1. BACKGROUND:

A revised technique for forecasting maximum wind velocities was used in 1969. It is based on a smooth curve extrapolation of central pressures along the forecast track. The forecast central pressure and forecast latitude are used as arguments to enter the JTWC pressure/wind correlation to obtain a forecast velocity. Modification of this initial forecast velocity is made subjectively according to the storms position with relation to the subtropical ridge, divergence patterns along the track, cloud organization as depicted by satellites and the sea surface temperature gradients when appropriate.

2. DISCUSSION:

Errors in forecasting by this technique result from:

- a. Normal instrument and/or reporting error in central pressures reported by reconnaissance aircraft.
- b. Latitude error in the forecast track.
- c. Failure of the intensity curve to follow the pattern established during early phases of the storm.

Aircraft dropsonde pressures are used on the confidence level of ± 5 mb. Both instrument error and minor differences in the placement of the dropsonde relative to the absolute minimum pressure in the eye on consecutive soundings are included in this confidence level. An analysis of the past several soundings is used to determine a consistent trace. Low level aircraft penetrations with direct readings of pressure improve the confidence level somewhat and provide anchor points for the tendency curve.

Errors in forecast latitude displace the entry on the pressure-wind correlation graph but generally contribute only 5 knots or less to the total error.

The primary source of error resulted from the breakdown of the extrapolation assumption when, as with typhoon Ida, a 55 millibar deepening was observed over an 18 hour period. Some typhoons go through more than one phase of intensification or do not follow a simple intensification-decay cycle.

3. DATA:

Table 3-1 records the 1969 season verification of maximum wind forecasts at warning time and all forecast times.

Figure 3-1 is the 24 hour maximum wind forecast

verification for individual typhoons of 1969.

Figure 3-2 is the frequency distribution of errors for 12, 24, and 48 hour forecasts of maximum winds.

Table 3-2 records the 1966 season verification for purposes of comparison.

4. ANALYSIS:

During the first 48 hours of each forecast period in 1969 absolute mean error increased at a mean rate of 2 knots every 6 hours from an initial error of 4.9 knots at warning time. The algebraic mean error was minus in all time categories indicating a forecast bias on the low side. The low bias increased from 1.9 knots at warning time to 6.8 knots at 48 hours.

The largest intensity errors were associated with the two most intense typhoons (Viola and Elsie), together with Typhoon Ida whose rate of intensification was unusually rapid and with Typhoon Susan, an off-season typhoon that ignored climatology in reaching 105-knot sustained velocity. Only these four typhoons significantly exceeded the mean absolute 24 hour forecast error of 13.7 knots.

The 24 hour intensity error distribution ranged from -45 to +35 knots with the median forecast 5 knots low and three-fourths of the forecast errors falling between -25 and +15. The 48 hour intensity error distribution ranged from -55 to +60 with the median forecast 5 knots low and three-fourths of the forecast errors falling between -35 and +10.

It is evident from the appearance of the forecast error distribution curves (Figure 3-2) that maximum wind forecast error increases with time and shows little skill at 48 hours. The median 12 hour forecast is accurate within ± 10 knots; the median 24 hour forecast is accurate within ± 37.5 knots.

In order to evaluate the relative success of the central pressure forecasting technique, the same analysis was made of the 1966 season accuracy of forecasting maximum winds. The results are reported in Table 3-2. Comparison shows a significant improvement in 1969. This is attributed to increased emphasis on forecasting maximum wind velocity and the effectiveness of the central pressure technique devised for this purpose.

5. CONCLUSIONS:

Forecasts of maximum wind for 12 and 24 hour time periods in 1969 have mean absolute accuracies of 9.0 and 13.7 knots respectively with a 5 knot bias toward underforecasting. These figures reflect a significant improvement over the 1966 season and indicate that the procedure described in this section is effective.

6. ACTION:

Continued use of the central pressure method of forecasting maximum winds is indicated for 1970 with an attempt to correct the tendency for slight underforecasting.

a. The algebraic mean values might suggest that forecasts could be improved in 1970 by merely increasing all forecasts by 5 knots, however, the frequency distribution in Figure 3-2 shows a modal value at zero error. Simply displacing the complex curve five knots to the right would not improve the distribution significantly. If the curve were pictured as symmetric with the errors on the positive side, the excess of forecasts in the range 10 to 25 knots too low becomes evident.

b. A study of these cases is indicated as the best way to improve performance in 1970. A further improvement may be realized from a climatological approach to mean rates of intensification. The climatic average values for the season used as minimum intensification forecasts should reduce the number of underforecast cases and produce a slight positive bias in mean values with a better centralized distribution.

FIGURE 3-2

B. A Discussion of Tropical Cyclone Forecast Verification Methods and Seasonal Differences in Forecasting Difficulty.

1. GENERAL:

a. Mean Error: The verification method for tropical cyclone forecasts used since the establishment of JTWC has been mean absolute error, with the 24 hour error receiving the most attention. (See Figure 4-1)

b. Right Angle Error: Recognition of some basic inadequacies of the mean absolute error led to addition of the right angle error charts (See Figure 4-3) to depict track forecasting ability apart from speed errors.

c. Median Error: Occasional large forecast errors contribute disproportionately to the annual mean error as seen in Figure 3-3. All mean values are greater than their corresponding median values. In 1969 the median error for the over 200 MI cases was 265 MI. Six errors of 70 MI are needed to balance 200 MI errors. The extreme effect of this could be seen in 1960 when multiple storms, overtaxed reconnaissance resources and erratic tracks combined to produce more large forecast errors and resulted in a spread of 46 N.M. between median and mean values. Median error provides a more conservative and meaningful measure of forecast accuracy for the season. Since median error represents the 50 percent confidence level, any desired specific and significant point in the frequency distribution of errors (67%, 75%, 80% or 90%) could be selected as a more valid measure of skill than the mean absolute error. The few large forecast errors that do occur would contribute equally to the combined figure on a one forecast-one vote basis. It is interesting to note that both 1968 and 1969 median scores of 97 N.M. were records for the 11 year period of record.

d. Seasonal Differences: The increased difference in 1969 between the median score of 97 N.M. and the mean score of 111 N.M. illustrates the influence of a few large errors on the annual mean in a "light" typhoon year. The 1968 and 1969 seasons both had six recurving typhoons and a similar number of opportunities for large error during recurvature or on northeasterly accelerating storms even though the total number of warnings issued in 1969 was only about half of the 1968 total. Through midseason 1969 including Typhoon Doris the JTWC absolute mean error was 89 N.M. The influence of recurving Typhoons Grace, Helen, Ida, June, and Kathy was not balanced by any straight-running, late-season cyclones. The year ended with a respectable but disappointing 111 N.M. mean error. The potential for breaking 100 N.M. in mean error for a season remains good but depends on limiting the larger errors and the chance occurrence of well-behaved cyclones. This illustrates a basic difficulty in evaluating forecaster performance from year to year in the tropics. A sample of 100 tropical cyclones might constitute a representative sample of all situations

24 HOUR MEAN AND MEDIAN ERRORS FOR JTWC TYPHOON FORECASTS

FIGURE 3-3

faced by the forecaster at one time or another, but a one-season sample of 20 or 30 cyclones is liable to contain a disproportionate number of recurving or erratic cyclones, resulting in a relatively high mean error. A sample containing straight-running cyclones, on the other hand, would produce a cushion of better than average forecasts. A method of evaluation including a measure of forecast difficulty would provide a more realistic appraisal of forecaster performance.

e. Displacement as Measure of Difficulty: A skill-scoring method sometimes mentioned for extratropical storms is based on error as a ratio of actual displacement during the forecast period. This method was used by LCDR Jerry Jarrell of Naval Weather Research Facility to examine JTWC annual forecast verifications from 1959 through 1967. (unpublished) The study has been updated for 1968 and 1969 and is presented graphically in Figure 3-4. The assumption made in this approach was that if a cyclone moves 500 N.M. in a 24 hour period, an error of 100 N.M. shows more skill than if the cyclone moved only 250 N.M. in the same period. In this system forecast errors are expressed as miles of error per mile of movement rather than the usual miles of error per 24 hour time period. In the first case the error rate would be $100/500$ or .200. The error rate of the second example would be $100/250$ or .400.

An implication of this system applied to individual forecasts is that slow-moving storms are easier to forecast than fast-moving storms. Such is not always the case, as illustrated by recurving storms which execute the greatest change of direction and present the most difficult forecasting situation while moving at their slowest speed. The error-producing combination of deceleration, rapid change of direction and then acceleration challenge the ability of any forecaster. Even though the 24-hour distance moved in a recurve track is the same as that on a straight track, the recurving storm is a much more difficult one to forecast. A quasistationary storm could never score well in the system because of the small denominator in the skill ratio. An excellent verification error of 50 N.M. made while the storm only moved 75 miles would not appear to have much skill. Applied to yearly mean values the system may avoid objections raised on the basis of individual forecasts. In the application of this technique to JTWC forecasts the mean displacement value and mean error are used to produce mean error ratings for each year. The variability of individual years in mean displacement values is evidence of significant differences in mean storm behavior from year to year. Under this rating system the 1969 season with a mean 24-hour speed of 12.4 knots for all typhoons would be more difficult to forecast than the 1968 season when a mean 24-hour speed of 9.2 knots was recorded. Compared with the past 11 years the 1969 season ranked 1st in difficulty and 1st in accuracy by the mean error to displacement ratio.

f. Objective Technique Scores as a Measure of Difficulty: A second indication of basic differences between

MEAN ERROR TO DISPLACEMENT RATIO

FIGURE 3-4

seasons is the variability noted in extrapolation and Arakawa objective technique scores in Table 3-3. The samples used in constructing the table included forecasts for tropical cyclones of all classes. (The JTWC values in this sample therefore may differ from official verification figures which include only those cyclones reaching typhoon strength.)

EXTRAPOLATIVE TECHNIQUE SCORES

YEAR	JTWC	EXTRAP	ARAKAWA
1967	121 NM	136 NM	NOT USED
1968	103 NM	108 NM	119 NM
1969	121 NM	131 NM	137 NM

TABLE 3-3

Extrapolation as used at JTWC includes a considerable amount of subjective judgement by the forecaster. The extrapolation forecast is usually the starting point for each official forecast. The fact that official forecasts have improved upon intelligent extrapolation by 5% in 1968, 9% in 1969 and 11% on a small sample in 1967 indicates a consistent mean skill on the part of the JTWC forecasters to do what they purport to do-forecast typhoon movements. A function of the difference between extrapolation error and mean error might serve as a measure of forecaster skill and JTWC performance. The Arakawa technique has consistently proved to be the best of truly objective techniques. This method eliminates the subjectiveness of extrapolation and may reflect the differences in difficulty between seasons better than any other simple method. The technique is firmly based in extrapolation. Errors recorded by this technique should be a good measure of the amount of nonsteady state change occurring. The 1969 mean Arakawa error of 137 N.M. compared to the corresponding 1968 value of 119 N.M. is interpreted to indicate that 1969 cyclones were more irregular in movement than those of the previous year, a fact well supported by personal observation.

2. CONCLUSIONS:

- a. An objective means of rating the difficulty of a typhoon season should be considered in addition to the single value of mean or median accuracy. The Arakawa technique is favored for this purpose.
- b. Median scores should be included in future annual reports as an alternate measure of forecast accuracy.
- c. The error to displacement ratio is not considered an indicator of forecasting skill, but displacement serves to point out the differences in storm behavior between one season and another.

C. Frequency Distribution of Error in JTWC Official Forecasts.

1. BACKGROUND:

Operational use of JTWC tropical cyclone warnings requires an appreciation of the frequency and nature of forecasting error likely to be encountered. This article is an effort to describe the frequency distribution to form a realistic basis of understanding for both the operational user and the JTWC forecaster.

2. PROJECT SCOPE AND DESIGN:

Mean 24-hour absolute errors on all storms designated as typhoons from 1959 to the present were counted and totaled by 10-knot intervals. The total frequencies were graphed and a smooth-curve analysis made (See Figure 3-5). A total of 4236 forecasts were included in the study. In order to provide an operationally useful tool the individual interval totals were converted to cumulative percentages for two periods: 1959-1967 and 1968-1969. (See Figure 3-6.) It is difficult to estimate whether the improved performance of the last two or three seasons can be maintained in future typhoon seasons. Both curves have been presented to show the long-time and recent experience.

3. DISCUSSION:

The cumulative percentages on the Y-axis can be used as desired levels of confidence to find the error margin in N.M. associated with this confidence level on the X-axis.

CONFIDENCE TABLE

LEVEL	59-67 (NM)	68-69 (NM)	IMPROVEMENT
50%	118	97	17.8%
67%	162	126	22.2%
75%	186	147	21.0%
80%	206	164	20.4%
90%	260	220	15.4%

TABLE 3-4

FORECAST ERROR FREQUENCY DISTRIBUTION 1959-1969

FIGURE 3-5

CUMULATIVE PERCENT OF FORECAST ERROR BY MILES OF ERROR

FIGURE 3-6

4. CONCLUSIONS:

a. It is noted that even though median and modal scores have reached record accuracies in 1968 and 1969, they don't measure the full extent of the forecast improvement realized. The maximum improvement is recorded near the one sigma level with over 22% improvement made in two-thirds of all forecasts.

b. The area of major improvement in the curve was between 40 N.M. and 160 N.M. and in this area represents a 30 to 40 N.M. increase in confidence level.

c. The failure to limit large errors is evident as the 90% and greater confidence levels are entered. Less improvement has been made in the upper 10 percent than in the average forecast range.

d. The incidence of errors exceeding 200 N.M. has been reduced from 21% to 12% but remains the necessary area of concern both because of the disproportionate influence on mean values and the potential for severe weather damage due to lack of adequate or timely warnings.

e. Very little improvement has been realized in the upper 5%. About 15 or 20 forecasts per year are so unpredictable that 24-hour errors will exceed 300 N.M.

f. In addition to this graphic approach to confidence level, the nature of each forecast situation should be considered. A storm moving in a northeasterly direction is, for instance, less accurately forecasted than other situations.

D. Causes and Cures for Forecast Errors Exceeding 200 N.M.

1. GENERAL:

A study of errors over 200 N.M. for the 1968 season was made to determine contributory factors and identify areas of possible improvement.

It was noted that the individual characteristics of each storm predispose large forecasting errors. Eleven of the 20 typhoons of 1968 had no forecasting errors greater than 200 N.M. The nature of each storm is, however, more a matter of hindsight rather than an evident feature of a storm prior to onset of looping, acceleration or generally erratic movement. Errors over 200 N.M. occur during all phases of the life cycle of tropical cyclones. In 1968 the early phases of a storm accounted for one-fourth, the late phases for one-fourth and the mature stage for the remaining one-half of large errors. The six identified factors contributing to large errors were:

- | | |
|--|-----|
| a. Forecaster Technique | 1/6 |
| b. Misleading Recon Data | 1/6 |
| c. Lack of Recon Data | 1/6 |
| d. Looping Motion or Quasistationary Periods | 1/6 |
| e. Acceleration on Northeasterly Track | 1/6 |
| f. Unusual Motions to Southwest or Sharp
Recurvature etc. | 1/6 |

Fujiwhara motions would also result in large errors but have not been common in 1968 or 1969.

Improvement of individual forecasts in the six categories is the present subject of JTWC operational research. The study of forecaster confidence reported in this annual points up the basic inability of the forecaster to anticipate large errors in many situations. Even under those circumstances when he can recognize the potential for large error, he is able to limit his error to average values in only half of the cases.

A forecaster's handbook for JTWC is being prepared as an aid to improve forecaster technique in minimizing these errors, particularly those resulting from misleading reconnaissance data.

The lack of reconnaissance data during the first 12 to 18 hours of warning of many developing storms is common. When a daylight investigation locates a depression, continuous reconnaissance is generally planned for the following morning. If the cyclone is moderately well developed when first located

or forecasted to develop rapidly, fixes are requested as soon as possible. During the initial period of development prediction of the direction of movement of tropical cyclones is frequently not very successful. Only after two or three "fixes" are we able to state with good confidence where the cyclone is or is going. The selection of the initial track is made on the basis of climatology, synoptic steering, and various objective techniques. Because of aircraft scheduling problems and the need to place cyclones in warning as soon as their development can be predicted, only small improvement can be expected in this area in the future.

Looping motions are a two-edged sword to forecasting accuracy. The sometimes sudden deceleration finds two or three forecasts far overshooting the storm and a consequent acceleration out of the loop leaves two or three quasistationary forecasts far behind. A study of loop duration, exit speeds and directions and a means of anticipating the breakout will be undertaken to provide a degree of error reduction in this difficult situation.

A study of accelerations on northeasterly tracks reveals a persistent underforecasting of northeast movements during 1968 and 1969 as well as in many years past. The average 24 hour error for northeasterly moving storms in 1968 was 156 N.M. on 52 cases. The 1969 average of 127 N.M. for 45 cases was some improvement, but forecasts remained persistently behind actual acceleration. During 1969 ten of forty-five northeasterly forecasts were in advance of actual movement, none by more than 65 miles. In 1968 ten of fifty-two forecasts were in advance of actual movement, six of them on the same storm and three of these 160 to 180 N.M. in advance of actual movement.

The experience of 1968 and 1969 is being used to identify storms with an expected accelerating track to the northeast and to compensate for the persistent underforecasting of movement seen in past years in 1970 operational forecasting.

The final category of movements to the southwest, sharp recurvatures and other unusual actions will continue to produce a few large errors. The best hope for improvement in these storms that fail to follow extrapolation may be found in the analog technique now under development.

A follow-up study in 1969 found that three typhoons accounted for 72% of the 24-hour errors over 200 N.M. and all of the 24-hour errors exceeding 300 N.M. Elsie, Grace and June were the misbehaving ladies. Elsie settled down after a rather unpromising beginning but Grace and June remained erratic throughout their lifetimes.

E. A Comparison of Objective Techniques for Typhoon Movement.

1. STATUS:

Forecasts using seven different objective techniques were used and verified for all four warning times for all 24 hour forecasts issued by JTWC in 1969. Techniques showing the best results in 1968 were retained and those failing to show promise were discontinued.

2. 24 HR OBJECTIVE TECHNIQUES:

- a. JTWC - official forecast for comparison.
- b. EXTRAPOLATION - a semi-objective method by which forecast points are determined by recent past values of position, speed and direction.
- c. ARAKAWA - grid overlay values of surface pressure are entered into regression equations and hand computed.
- d. 700 mb PROG - HATRACK forecast based on 700 mb SR forecast fields.
- e. 700 mb PROG MOD (12 Hr) - (d.) is modified by twice the recent 12 hr vector error.
- f. 500 mb PROG - HATRACK forecast based on 500 mb SR forecast fields.
- g. 700/500 mb PROG RENARD - method using HATRACK 700 mb longitude and HATRACK 500 mb latitude (reported in 1968 annual).

3. MODIFICATION TECHNIQUES:

a. A single correction vector equal to twice the most recent 12 hour error correction vector is applied to the 700 mb prog forecast to produce the 700 mb prog mod forecast.

b. A 12 hour history position is provided as an input to the TYRACK program. The apparent speed and direction over the past 12 hours is computed and used to select the best steering level and to correct the forecast steering of that level for observed differences from history.

4. TESTING AND RESULTS FOR 24 HOUR FORECASTS:

A homogeneous sample of 210, 24 hour forecasts, for tropical storms and typhoons was assembled for 1969. Results are summarized in Table 3-5. The following general observations are offered:

OBJECTIVE METHODS STATISTICS 1969

TABLE 3-5

* 700PROG MOD (12) has only 124 cases. Comparisons cannot be made on a homogeneous basis between this and other objective methods. Many of the missing forecasts involved extreme forecasts and were omitted as not meaningful.

a. JTWC official forecasts are again significantly better than any single objective technique.

b. Extrapolation continues to be the single most reliable objective technique. The 1969 extrapolation error of 142 N.M. increased 28 percent over the 1968 value of 111 N.M. The improvement over extrapolation of the JTWC official forecast increased from 5 percent in 1968 to 13 percent in 1969.

c. Arakawa forecasts remain very close to extrapolation and increased 16 percent over the 1968 value of 121 N.M.

d. The HATRACK 700 mb prog again verified better than the 500 mb prog but total error of 235 N.M. is excessive.

e. The 700 mb prog mod (12 Hr) - again improved on the performance of the unmodified forecast with performance approaching that achieved by the Arakawa surface pressure method.

f. The 700/500 mb prog Renard method again improved upon the performance of both the 700 mb and 500 mb HATRACK forecasts by 7 percent over 700 mb and 19 percent over 500 mb.

g. The TYRACK forecasts were disappointing in total accuracy but provided the most realistic and usable track forecasts during the season, particularly for recurving storms. Large speed errors continue and show need for additional program controls. The continued improvement in 48 and 72 hour right angle error is in part due to guidance from the TYRACK track forecast.

h. Individual forecasts in a non-homogeneous sample were examined from the viewpoint of determining the forecast method producing the individual absolute best verification score. The results are presented in Table 3-6.

TABLE 3-6

The JTWC forecast does not always produce the absolute best forecast but is more consistent. Cases where extrapolation or Arakawa produced a best forecast often involved a difference of only a few miles from the official forecast. Mean deviation from the JTWC forecast in these cases was

48 N.M. for extrapolation and 53 N.M. for Arakawa. This points out an area of potential improvement since 115 of 282 cases could have been improved by closer use of extrapolation or Arakawa objective techniques. Since all forecasts begin with extrapolation the remaining 167 forecasts must represent situations where extrapolation was correctly modified to produce a better official forecast. Further research aimed at developing procedural rules for limiting the deviation from Arakawa and extrapolation should improve some of the 18 cases in which the JTWC error was over 100 N.M. greater than extrapolation or Arakawa.

i. Tables 3-7 and 3-8 present stratified analyses of 1969 objective methods. Table 3-9 applies stratification by latitude to JTWC official forecasts. The 1969 sample is not large enough to guarantee representative figures in all stratifications but most results support previous observations. The following tentative conclusions based on stratification are offered:

(1) All computer methods except the 700 mb prog modified for 12 hour error performed best at higher latitudes with northeasterly moving storms. Arakawa did not work well at all for these storms. Extrapolation error was high due to acceleration. The 700P(MOD) provided a fair overall forecast for northeasterly moving storms.

(2) The most forecastable storms were those south of the ridge line. JTWC, Arakawa and extrapolation scored best on these. The 102 N.M. error for Arakawa on 77 westerly moving storms is very convincing.

(3) Stratification by wind extensity shows improved steering with increased intensity for all except the extrapolative techniques.

TABLE 3-9

F. Confidence Forecasting.

1. BACKGROUND:

Forecaster confidence in his product is an often discussed parameter. If a forecaster were able to anticipate his good and bad forecasts, operational users would benefit from this information. In response to discussions of the 1969 Typhoon Conference an operational research project was designed to record and evaluate the accuracy of forecaster confidence at the time of forecast at JTWC.

2. PROGRAM SCOPE AND DESIGN:

The confidence forecast sample was 205 separate confidence forecasts from April through October of 1969. The sample included tropical storms as well as typhoons. The Director, Operations Officer or Typhoon Duty Officer completed a series of objective and subjective forecasts of confidence after each official warning but prior to the next aerial reconnaissance fix. The objective methods used were:

a. Area Climatology of Errors Based on Mean 1968 Experience: The assumption of this approach is that the difficulty of forecasting can be predicted from the location of the cyclone at the time of forecast.

b. Area Climatology by Category: This approach used the same data base as the first but makes only the category forecasts of average (110 N.M.) below average (70 N.M.) or above average (150 N.M.)

c. Mean Climatology: A representative mean climatology of 110 N.M. was applied to all forecasts.

d. Persistence: The 24 hour error determined at forecast time was forecasted to persist for the next 24 hours.

e. Subjective Forecast: Forecaster confidence in the subjective feeling a TDO has about his knowledge of where a cyclone is now, where it has been and where it is going. The following values were suggested from the 1968 season:

1st three warnings (no good 12 hour history)	150 N.M.
20 to 30 knot winds at forecast time	120 N.M.
Northeasterly movement	140 N.M.
Best confidence limit	40 N.M.
Worst confidence limit	200 N.M.

The original impetus for this study was the understand-

able desire to express statistically the increased confidence that was believed to accompany the reduction in forecasting error noted in the last few years thus enabling closer passage by mobile operating forces to tropical cyclones when forecaster confidence was better than average.

3. ANALYSIS:

a. General: Only the subjective method was significantly better than the other four methods tested. On the whole, forecasters' subjective estimates tended to be conservative, averaging 9 N.M. greater than observed mean error. Seventy-five percent (75%) of the confidence forecasts verified with errors no more than 20 N.M. greater than the forecast value. This figure compares with seventy-six point-five percent (76.5%) that would have verified under the same ground rules using a mean error value of 105 N.M. for all forecasts. The second method approximates the manner of applying confidence implied in current SEVENTH FLEET Operations Orders and presents a fair argument for retention of the present doctrine.

The relatively poor performance of the error forecasts by geographic area of origin is undoubtedly due in part to the limited sample size of the error climatology. Whenever 1968 error history was not available the mean value for 1968 was substituted. The relatively poor final performance of the area climatology, both mean values per 2 1/2 degree square and three category assignment, indicates negative correlation between forecast errors in the same geographic location from one year to the next. A tentative hypothesis for these data is that geographic errors are less significant than dynamic errors associated with storm intensity, speed of motion, direction of motion and its relation to large scale synoptic features of current weather charts. The expansion of error climatology based on geographic area would eventually produce a forecast showing some skill due to a concentration of storms with similar characteristics in the same area, but a more direct approach considering the dynamics of intensity or speed and direction of motion should be superior meteorologically.

The poorest of the objective methods is the persistence forecast. The results here indicate that large errors or small errors are unlikely to repeat themselves over a 48 hour period and also that forecasting of extreme values results in larger errors than forecasting mean values. We must conclude with some conviction that yesterdays performance is less indicative of todays confidence than is last years mean error value.

Even though the mean value of subjective forecaster confidence shows little skill over last years single mean value, the possibility of skill in one or more confidence categories is worth investigating.

b. Better Than Average Confidence (25 N.M. or less): Forecasts of good confidence are useful if (1) they can be reliably made and (2) they can result in a significant change in operational decisions. Relative to the first criterion, 12 of 49 confidence forecasts (24% of better than average confidence (85 N.M. or less) verified with greater than average error (135 N.M. or more.) From this we might describe a 76 percent confidence level that our forecast of "better than average" will verify as "average" or "better than average." Relative to the second criterion the best confidence used during the period was 50 N.M. The median error of the confidence forecast was 42 N.M. An operational decision at the 75 percent confidence level would thus involve the difference between a single mean error of 105 N.M. and the adjusted subjective forecast of 92 N.M. A maximum reduction of a "clearance criterion" for tropical storms of only 12 percent or 13 N.M. would result. Any of the 12 "bust" forecasts from the "better than average" forecast group might have encouraged a closer approach than would otherwise be considered prudent to the subsequent track of a typhoon if the confidence forecast were used in determining an evasion course. It is doubtful if the potentially small gain justifies the loss of confidence level.

c. Average Confidence (90 to 130 N.M.): One hundred five (105) of the two hundred five (205) forecasts in the sample were forecasted to be in the average range (90 to 130 N.M.) and only 21 of them (20%) verified with greater than average error. One would normally expect many more "bust" forecasts from the average confidence group than from the better than average group if predictable skill were involved.

d. Below Average Confidence (135 N.M. to 200 N.M.): Twenty-four (24) of fifty-one (51) below average confidence forecasts (47%) verified correctly in the above average error group suggesting considerable skill in the recognition of large error potential at the time of forecast. Even when circumstances of missing or questionable data create doubt in the forecasters mind and lead him to anticipate large potential errors, persistence works toward verifying a conservative extrapolation forecast. Verification of an expected large error with better than average accuracy is no indication of lack of forecaster skill. On the contrary it indicates that a difficult situation was recognized and correctly forecasted. The greater frequency of large errors in cases where they are expected would be valuable information to the Captain desiring to exercise all caution due an uncertain forecast of hazardous weather.

4. CONCLUSIONS:

a. Confidence as a forecast parameter is subject to the same range of inaccuracies experienced with other forecast parameters.

b. The best method of forecasting confidence found in the initial project was the subjective opinion of the forecaster.

c. The only occasion when a subjective confidence forecast showed significant skill was when large errors were anticipated.

G. Fujiwhara Effect - Case Studies.

1. INTRODUCTION:

There are many problems to be faced in tropical cyclone movement forecasting. One of these, which occurs only seldom but which is capable of injecting exceptionally high errors into movement forecasts, is the interaction of vortex centers with one another. This is often referred to as a demonstration of the Fujiwhara effect in honor of the first primary investigator of this phenomenon. This interaction or Fujiwhara effect is characterized by a cyclonic rotation of two vortex centers about some point located along a line connecting their two centers. This rotation is usually co-existent with a mutual attraction of the two vortex systems. The combined effects of rotation and attraction greatly affect forecast accuracy, since cyclone behavior deviates sharply from normal under these conditions.

Before forecast improvement can be achieved through practical application to compensate for the Fujiwhara effect, a better understanding of cyclone behavior under influence of binary interaction is necessary. To aid in this understanding, research was conducted on two cases of previous cyclone interaction. These cases were picked at random with the hope of obtaining cases representative of most occurrences.

Individual cyclone movement was investigated to see if it was feasible to combine cyclone rotation rates and some form of translation of a point common to both cyclones to obtain a reasonable estimate of actual individual cyclone speed of movement.

The first case investigated was that of Typhoons Kathy and Marie during the period 14/0000Z through 19/0000Z August 1964 (See Figure 3-7). The second case was that of Typhoons Marge and Nora during the period 24/1200Z through 28/1200Z August 1967 (See Figure 3-8).

The first case appeared to be a more classical example of binary cyclone interaction than the second case, but there was a definite interaction of the two cyclones in the second case also.

2. PROCEDURE:

The two cyclone tracks within each case were plotted on the same chart so that a visual representation of their relative interaction could be observed. Lines were drawn between each of the cyclone tracks connecting locations at corresponding times, so that angles of rotation could be determined. A midpoint between the cyclones along each connecting line was determined.

Though the use of the midpoint as the rotation pivot is a very simple method, it does not consider relative sizes of the interacting cyclones. Therefore a second set of rotation points was obtained to include a relative size factor. Many authors have theorized that rotation during binary cyclone interaction occurs about a point corresponding to the center of mass of the two interacting systems. Mass of any meteorological system is a very vague term and one which is hard to define. To incorporate this theory into an actual study, a previously suggested method using a maximum wind speed ratio was utilized using the following formula;

$$d_1 = \frac{DV_2}{V_1 + V_2} \quad [1]$$

where

d_1 is the center of mass location from cyclone 1.

D is the total separation distance of the two cyclones.

V_2 is the maximum wind speed of cyclone 2.

V_1 is the maximum wind speed of cyclone 1.

By using these two points, the midpoint and the center of mass point, rates of rotation were determined. Afterward the translation speeds of these points of rotation were added with the rotation speed in hopes that a good approximation of actual cyclone speed could be determined. A twelve hour time period was used for all calculations. The following formulae were used:

$$S = S_r + S_t \quad [2]$$

$$S_r = 1.4 \times 10^{-3} \propto \bar{r} \quad (\text{for 12 hour period}) \quad [3]$$

$$S_t = D^*/12 \quad (\text{for 12 hour period}) \quad [4]$$

where S : total speed of movement

S_r : speed of movement resulting from rotation.

S_t : speed of movement resulting from translation of the point of rotation.

\propto : angle of rotation over the 12 hour period.

\bar{r} : the average radius of rotation.

D^* : distance point of rotation moves in 12 hours.

NOTE: Direction of movement of the point of rotation relative to the direction of the cyclone rotation was not considered in calculated movement speeds.

3. DISCUSSION:

An analysis of the movement speed calculated by both the center of mass and the midpoint methods showed that in general the computed speed of movement was more accurate for the northernmost cyclone. The computed values for speed of movement for the southernmost cyclone were generally too high (See Figures 3-9 and 3-10).

One cyclone investigated, Typhoon Nora, fit these general observations but the calculated speeds were exceptionally unrealistic up to 27/0000Z. After that time calculated values compared favorably with the actual cyclone speed. At that time Nora became the northernmost cyclone of the pair and also began to show a slow intensification. This large error was probably caused by the fact that prior to 27/0000Z, Nora was just forming and moving very slowly. Her strength was only 20 knots or less during this period and she appeared to be no more than a weak, but well organized, tropical low.

Investigation of Case I (Typhoons Kathy and Marie) indicated that for Typhoon Kathy the center of mass point of rotation method gave exceptionally good results for the entire interaction period with an average error of only 1.5 knots. This was an average percentage of error of 27%. For Kathy the midpoint method gave good results also with an average error of 2.5 knots representing an average percentage of error of 36%.

For both methods, one time period was characterized by an unreasonable error. Estimated speeds for Kathy during the 12 hour period 17/1200Z to 18/0000Z were calculated as 7.5 knots and 7.1 knots for the center of mass method and the midpoint method respectively. During this time period Kathy was moving south, becoming the southernmost cyclone after previously being the northernmost cyclone. During this time the direction of rotation was perpendicular to the point of rotation movement therefore the rotation speed alone should have given the best estimation of the actual movement speed. The rotation speeds for the center of mass method and the midpoint method were 5.6 knots and 6.8 knots, respectively. These compared more favorably to the actual movement speed of 4 knots.

The average results for Typhoon Marie were comparable to the results obtained for Kathy with an average error of 2.7 knots when the midpoint method was used. This corresponded to an average percent of error of 32.9%. When the center of mass method was used a much greater average error of 5.9 knots and an average percent of error of 60.6% was obtained. A look at Figure 3-9 shows that after 17/0000Z the errors for the midpoint method decreased and remained fairly accurate. At that same time the center of mass method increased in accuracy but

after 18/0000Z the accuracy decreased significantly. It was found that for every time there were poor comparisons the cyclone was either moving at large angles to or in the opposite direction to the movement of the rotation point. This indicates that a component of the point of rotation movement speed relative to the direction of movement of the cyclone should be considered in order to achieve the best results.

It was also observed that the original northernmost cyclone actually slowed to a minimum movement speed about 6 to 12 hours after the calculated speeds of both the midpoint and the center of mass methods indicated a minimum in speed. At the time the two interacting cyclones became east and west of each other the cyclone moving south tended to slow sharply in movement while the cyclone moving north began to accelerate. Shortly before this the point of rotation either slowed in movement speed or became erratic in movement.

Investigation of Case II (Typhoons Marge and Nora) indicated that the midpoint method gave slightly better results for both cyclones considered together, but neither method gave good results for Nora until 27/0000Z. As mentioned earlier, before this time Nora was only a weak developing tropical low and as such her movement is considered unrepresentative of normal cyclone movement under Fujiwhara effects.

Excluding the results for Typhoon Nora, the comparison of actual versus computed speeds of movement for this case compared favorably with those of Case I. The speeds of movement calculated for Typhoon Marge indicated that the center of mass method gave slightly better results for the overall investigated time interval. The center of mass method gave an average error of 2.3 knots as compared to 2.5 knots for the midpoint method. The corresponding average percents of error were 31.2% and 38.7%, respectively (See Table 3-10). The midpoint method gave exceptionally good results during the first part of the investigation period up to 27/1200Z with an average error of 1.0 knots and an average percent of error of 8.4%. Both methods were very good until 27/0000Z.

After 27/0000Z, Marge became the southernmost cyclone as the two cyclones slowly rotated. After that time the cyclone's movement was perpendicular to or in the opposite direction of the rotation point movement. This case, therefore, also indicates that more accurate results could be obtained by using the component part of the rotation point movement corresponding to the cyclone movement.

Although Nora was very weak during the initial time period of this case study, she evidently had some definite influence on the movement of Typhoon Marge. Nora was too weak in comparison to Marge to ever cause a full rotation but she was able to alter the track and speed of Marge (See Figure 3-8). At the time when Nora moved north of Marge's 090° bearing, attraction of the two cyclones seemed to cause a rapid decelera-

tion of Marge and shortly thereafter Marge experienced a change in direction to a north of west course.

As noticed in Case I, the points of rotation for Case II slowed in movement or changed direction abruptly approximately 6 to 12 hours preceding a decrease in the speed of movement of the cyclone moving toward the south. (See Figure 3-10.)

The angle of rotation (α) is one of the major variables contributing to the estimation of a cyclone speed of movement while experiencing Fujiwhara effect. Since little is known about what elements cause significant changes in values of α , a short investigation of its characteristics evident in these two case studies was conducted. It appears that there is some influence on α caused by changes in intensity differences of the two interacting cyclones and changes in the average distance of separation. An investigation of this variance of α in relation to values of intensity differences compared with cyclone separation indicated that an increase in α occurs with a decrease in separation distance and an increase in the intensity difference of the two cyclones. It also appears that very little rotation occurs at separation distances greater than 600 or 700 N.M. no matter what the intensity difference is. See Figure 3-11.

4. CONCLUSION:

The results of this research indicate that cyclone speed of movement during interaction can be closely approximated by theoretical calculations which combine the rotational effect of the cyclones and the translation of the point of rotation.

Results were exceptionally good when the cyclone was moving in the same direction as the point of rotation. It was also noticed that when a cyclone was moving in an opposite direction to that of the rotation point better results were achieved by subtracting the translation speed of the rotation point. For inbetween cases, such as when the cyclone was moving at angles to the direction of movement of the rotation point, calculated speeds would be improved by adding or subtracting only that component of movement speed of the rotation point that corresponded to the direction of movement of the cyclone.

Consideration of cyclone intensity by using the center of mass method was necessary only for cases of excessive difference in the intensity of two cyclones. Even for excessive intensity differences the midpoint method will generally give satisfactory results.

By using the translation of the point of rotation as a contributor to the cyclone speed of movement, we are assuming that the speed of movement of the rotation point is in direct proportion to the steering flow. We are also assuming that the steering flow is homogeneous for the entire rotating system, which requires the horizontal shear to be zero. This is a

tenuous assumption since horizontal shears are seldom zero over an area as large as that representing these rotating systems. Therefore it must be concluded that the presence of excessive or large horizontal shears can definitely inject significant errors into speed calculations.

It was noticed during analysis of computed cyclone movement speeds and the corresponding actual cyclone movement speeds that at the time the points of rotation began to slow in translation speed or became erratic in movement, the cyclone pairs reacted much in the same manner for both cases. At the time the point of rotation began to slow or became erratic, the cyclone moving toward the south slowed in movement within the following 6 to 12 hour period while the cyclone moving north began to increase in speed of movement within the next 6 to 12 hours. After firm substantiation by investigation of several more cases, this observed reaction could prove beneficial in the short range forecasting of changes in cyclone speed of movement of two interacting cyclones.

There are definite possibilities for future use of binary cyclone interaction theories for assisting in forecasting movements of interacting cyclones but considerably more research is needed before a reliable forecast tool evolves. From equations [2], [3], and [4], we can see that if S_r and S_t can be predicted with reasonable accuracy for a period of time, say 12 hours, then an average speed of movement of the cyclone can be obtained for that 12 hour period. Keep in mind that a component of S_t would have to be added or subtracted from S_r , depending upon an estimated direction of movement for the cyclone in question. It appears that a reasonable answer could be reached simply by adding S_t to S_r for a westward moving cyclone and subtracting S_t from S_r for an eastward moving cyclone.

Now that the use of the predicted S_r and S_t is necessary, we come to the perplexing problem of how a prediction of S_r and S_t can be reached. Although not researched in this study, it appears that a reasonable value for S_t could be reached by steering the rotation point with the integrated steering flow much as would be done for forecasting the movement of a single cyclone. (The possible errors in using this method were suggested earlier when discussing the assumption of a horizontally homogeneous atmosphere over the interacting system). Prediction of S_t is difficult enough but the prediction of S_r at this state of the art is even more difficult. From equation [3] it is noticed that a value for S_r is dependent upon the angle of rotation for a predetermined time period (α) and upon the average radius of rotation (\bar{r}). A reasonable value for \bar{r} can be reached by forecasting the expected distance separating the two cyclones, considering mutual attraction, and if desired, by also using an estimated intensity of each cyclone. A prediction method for α is the major "weak link" in the chain. Present knowledge of the mechanisms causing significant changes in the rotation rates remains at a rather primitive level.

It may be possible in the future to obtain a reasonable approximation for the angle of rotation from a graph similar to that in Figure 3-11. For this to be feasible, investigation of many more case studies will be required to increase the density of data points to obtain consistently reliable estimates of the angle of rotation.

As a result of this investigation, it is definitely indicated that cyclone movement during interaction can not be fully explained or forecasted by the use of simple techniques, but continued research in this area has good potential for assisting in lowering errors in the forecasting of tropical cyclone movement.

MOVEMENT ERROR (CALCULATED VS. ACTUAL)

		MIDPOINT		CENTER OF MASS

H. Climatology

1. TYPHOON FREQUENCY:

Typhoon frequency climatology was slightly decreased by the small number of occurrences experienced this season. The average annual typhoon frequency decreased from 20.6 at the end of the 1968 season to 19.9 at the end of this season (See Table 3-11).

2. TYPHOON DISTRIBUTION:

Figure 3-12 depicts the typhoon distribution of 347 typhoons which have been detected over the past 18 year interval. Notice that the months of high formation probability remain the months of July through November after the inclusion of 1969 typhoon data.

WESTERN PACIFIC TYPHOONS

1952 — 1969

FIGURE 3-12

I. Satellite Data Fix Accuracy.

1. BACKGROUND:

A study of satellite fix accuracy was presented in the 1966 Annual Typhoon Report. Since that time a new generation of space hardware and improved technology have been developed. This study was made to reflect any improvements in terms of fix data reliability.

2. METHOD:

Satellite bulletin fix positions were compared to the JTWC best track positions for the time of the satellite fixes. Results are reported in Table 3-12.

SATELLITE POSITION ERROR (N.M.)

	<u>1965</u>	<u>1966</u>	<u>1969</u>
NUMBER OF CASES	75	71	75
AVERAGE ERROR	81	49	39
MEDIAN ERROR	55	39	34
RANGE OF ERROR	0-425	5-219	5-105

TABLE 3-12

3. CONCLUSIONS:

Slight improvement since 1966 is indicated, however, 1969 figures were limited to storms whose best track wind velocities were 35 knots or greater. This eliminates the main source of disproportionately high errors during the formative stages and may account for some apparent gain in accuracy. The 1969 mean and median position errors represent the practical total resolution presently available from satellite systems relative to location of tropical cyclones.

CHAPTER IV

SUMMARY OF TROPICAL CYCLONES 1969

TYPHOONS OF 1969

SUMMARY OF WESTERN PACIFIC TROPICAL CYCLONES OF 1969

During 1969, the Joint Typhoon Warning Center issued 430 warnings on 13 typhoons, 6 tropical storms and 4 tropical depressions while in a warning status for 108 days. When compared with previous years, it is evident that 1969 was an unusually inactive year.

There were no tropical cyclones passed to JTWC from outside its area of responsibility and JTWC passed no tropical cyclones to other agencies.

There were two "Super Typhoons" (maximum sustained surface wind of 130 knots or greater) during the 1969 season compared with five in 1968 and four in 1967. Typhoon Elsie registered a 890 MB center pressure which is one of the lowest ever recorded in the Western Pacific.

The following figures and tables are provided to present representative statistical data from the 1969 tropical cyclone season and provide a ready reference for comparison with previous years.

Forecast positions for the 24, 48 and 72 hour forecasts are verified only as long as the best track analysis estimates winds in excess of 33 knots for tropical cyclones which reach typhoon intensity.

In addition to this method of verifying absolute error distance, a computation of closest distance to the best track (right angle error) has been included to indicate the demonstrated ability to forecast the path of motion without regard to speed.

The following tables and figures are presented to graphically depict the distribution of forecasting error in JTWC forecasts.

FORECAST VERIFICATION
AVERAGE ERROR (NAUTICAL MILES)

	<u>24 HR</u>	<u>48 HR</u>	<u>72 HR</u>
1950-58	170	---	---

CHAPTER V

INDIVIDUAL TYPHOONS OF 1969

NOTE. See Appendix A for definitions or clarification of words or phrases that appear in this chapter.

TYPHOON PHYLLIS - 01/17/0500Z TO 01/22/2300Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 24
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 15
3. DISTANCE TRAVELED DURING WARNING PERIOD - 1968 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 966 MBS AT 182100Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2819 M AT 182100Z
3. MAXIMUM SURFACE WIND - 085 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 240 MI

II. DEVELOPMENT

- A. INITIAL IMPETUS - LOW LEVEL SURGE INTO CYCLONIC CIRCULATION FROM THE SOUTH WITH SUBSEQUENT DIVERGENCE AT 200 MB LEVEL.

B. INITIAL SURFACE VORTEX

1. EMBEDDED VORTEX AT 140000Z
2. SURFACE PRESSURE LESS THAN 1006 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - SOUTHEAST
2. UPON REACHING TYPHOON INTENSITY - SOUTHEAST

III. FINAL DISPOSITION

- A. DISSIPATED OVER WATER

1. NUMBER OF WARNINGS ISSUED - 29
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 12
3. DISTANCE TRAVELED DURING WARNING PERIOD - 882 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 943 MBS AT 212130Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2615 M AT 222130Z
3. MAXIMUM SURFACE WIND - 105 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 240 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - 200 MB ANTICYCLONE OVER THE SURFACE CYCLONE

B. INITIAL SURFACE VORTEX

1. EMBEDDED VORTEX AT 160500Z
2. SURFACE PRESSURE LESS THAN 1007 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - SOUTHEAST
2. UPON REACHING TYPHOON INTENSITY - SOUTH

III. FINAL DISPOSITION

A. DISSIPATED OVER LAND

Map details include:
 - Latitude: 10°N to 20°N
 - Longitude: 110°E to 130°E
 - Landmasses: Philippines, Japan, China
 - Key locations: Manila, Hong Kong, Japan, Taiwan, Luzon
 - Track markers: Numbers (1-10), symbols (circles, squares, triangles) indicating storm intensity and position.
 - Annotations: "21/23Z 100", "24/17Z 100", "25/03Z 25", "22/23Z 100", "21/23Z 100", "20/23Z 100", "19/05Z 100", "18/05Z 100".

TYPHOON VIOLA - 07/21/2300Z TO 07/28/0500Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 26
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 18
3. DISTANCE TRAVELED DURING WARNING PERIOD - 1854 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 897 MBS AT 262100Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2137 M AT 262100Z
3. MAXIMUM SURFACE WIND - 130 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 420 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - 200 MB ANTICYCLONE OVER THE SURFACE CYCLONE

B. INITIAL SURFACE VORTEX

1. JUNCTION VORTEX AT 180000Z
2. SURFACE PRESSURE LESS THAN 1008 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

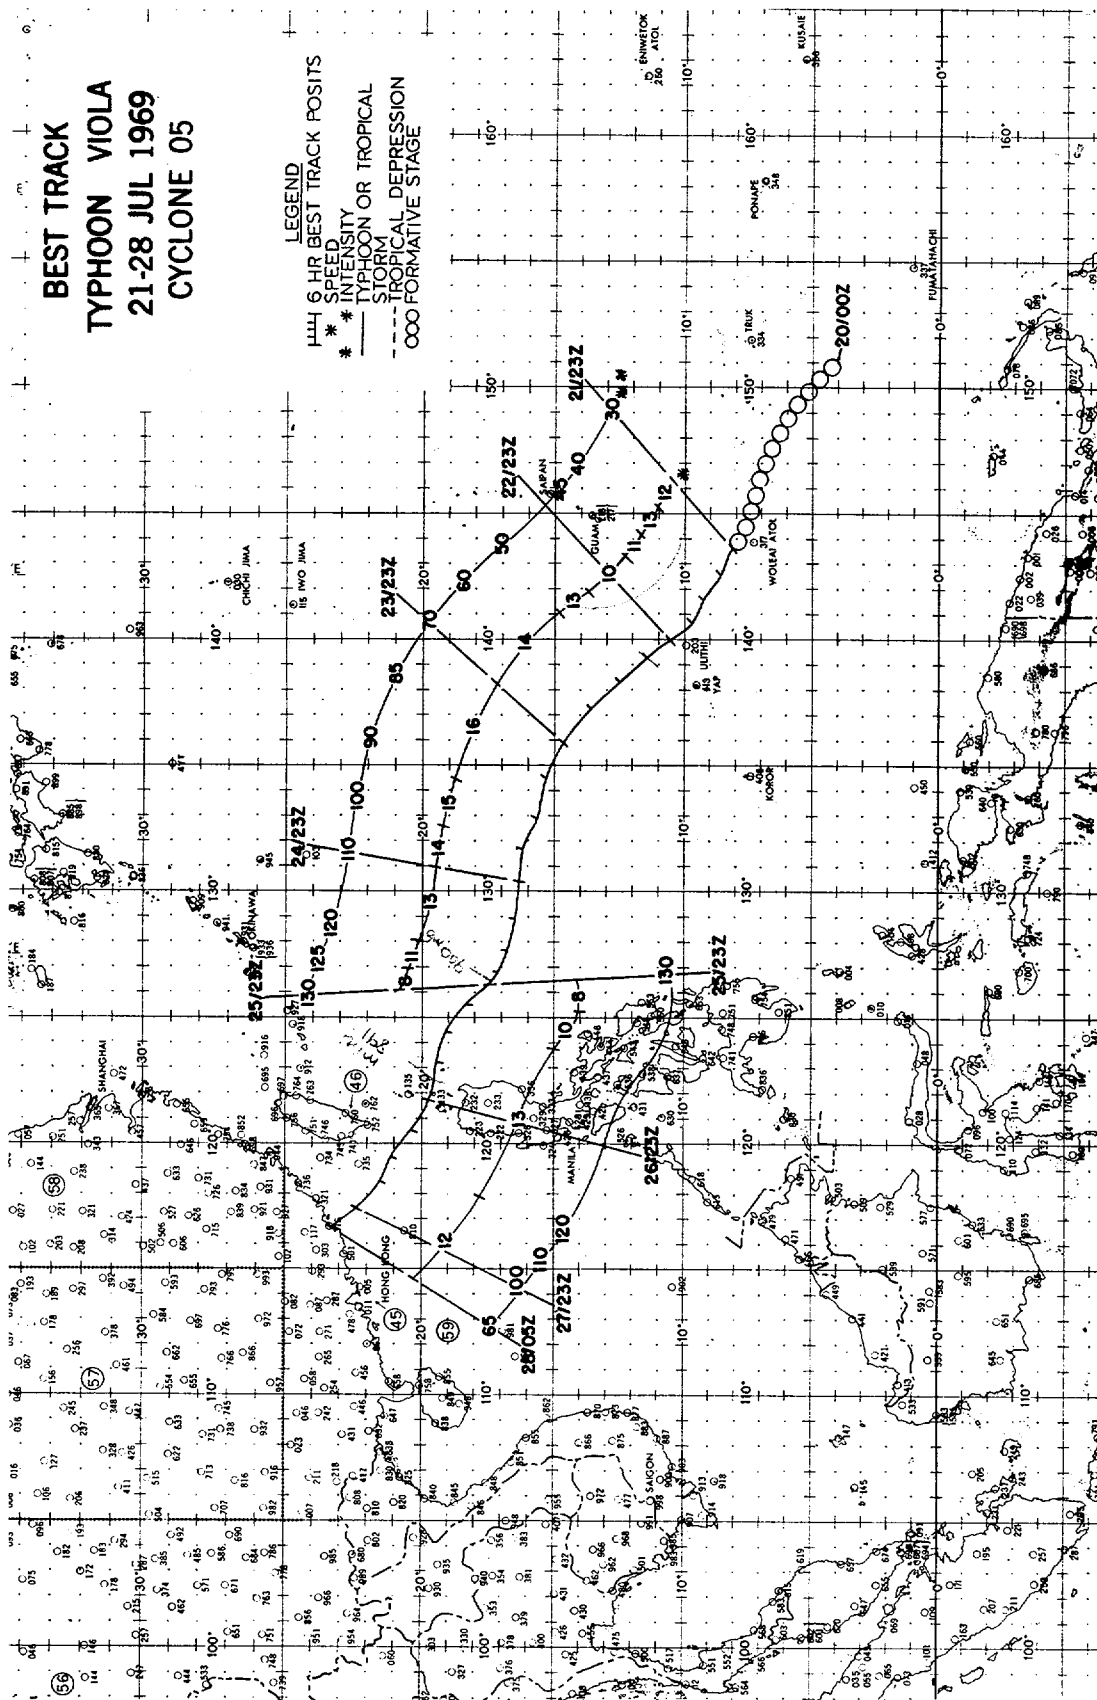

1. INITIAL - EAST
2. UPON REACHING TYPHOON INTENSITY - SOUTHEAST

III. FINAL DISPOSITION

A. DISSIPATED OVER LAND

TYPHOON BETTY - 08/05/0500Z TO 08/08/1100Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 14
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 04
3. DISTANCE TRAVELED DURING WARNING PERIOD - 1242 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 962 MBS AT 080200Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2796M AT 072110Z
3. MAXIMUM SURFACE WIND - 070 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 360 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - UNSTABLE EASTERLY WAVE UNDER 200 MB DIVERGENCE

B. INITIAL SURFACE VORTEX

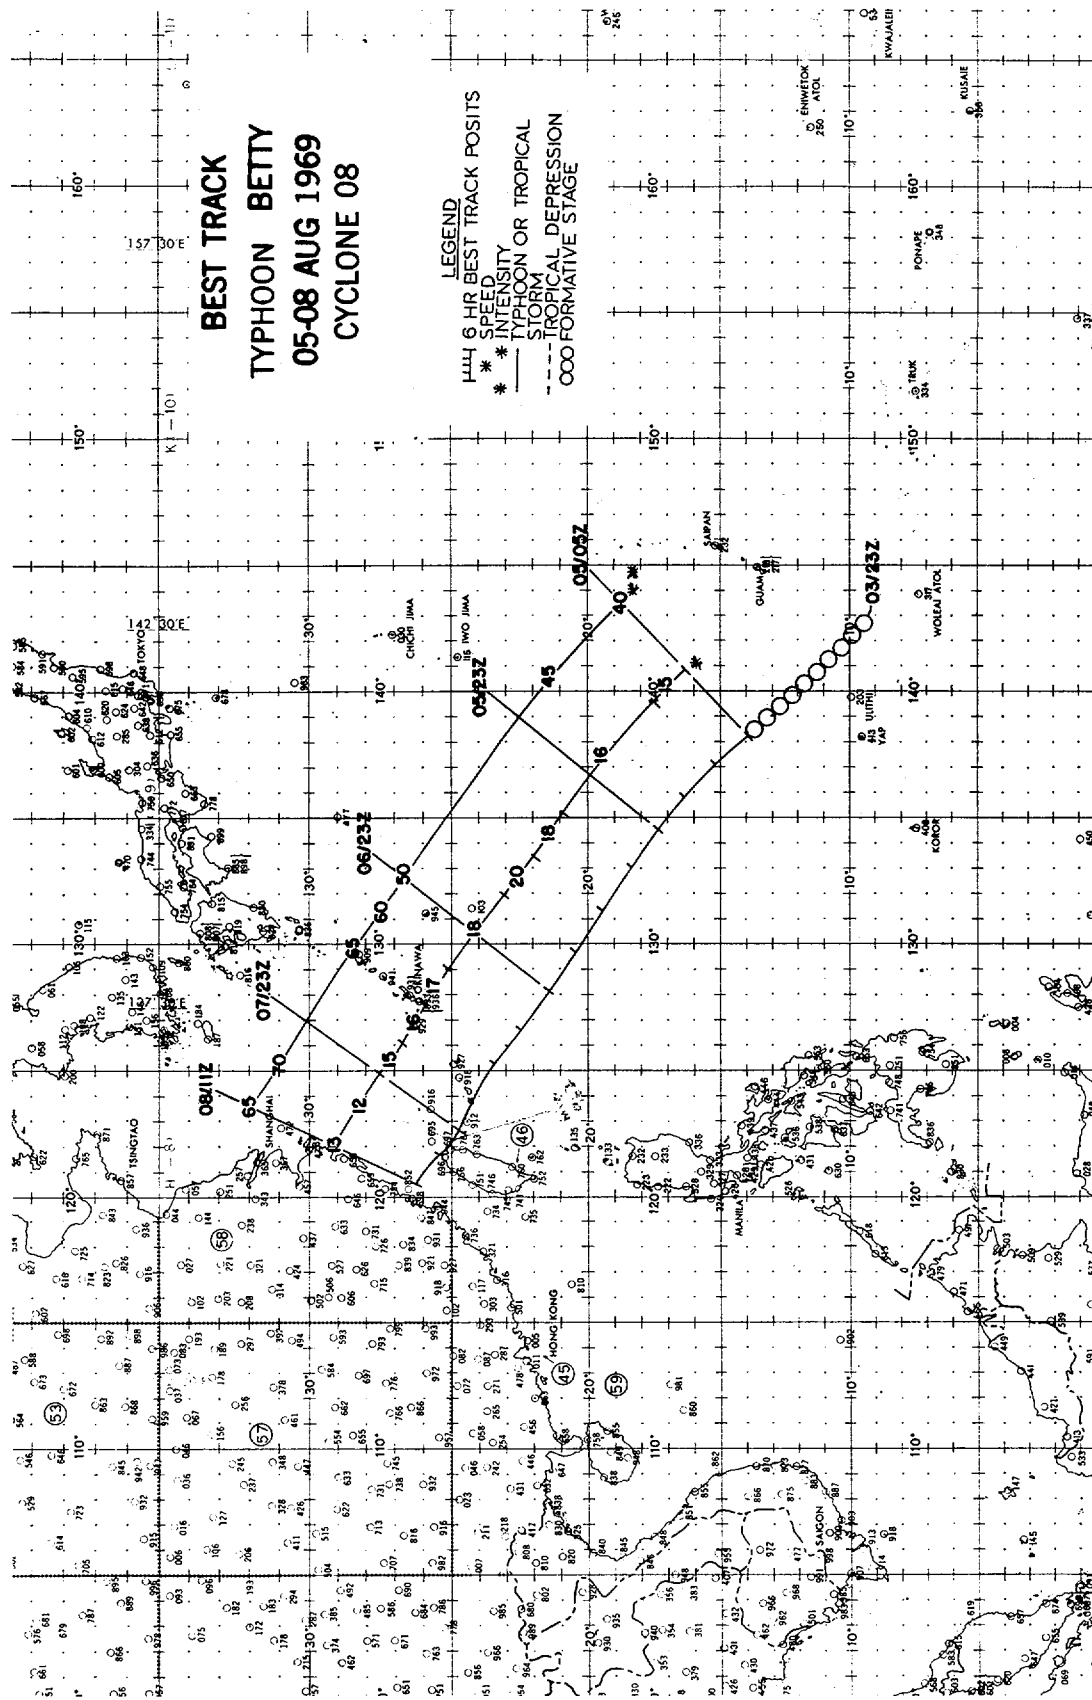

1. JUNCTION VORTEX AT 021800Z
2. SURFACE PRESSURE LESS THAN 1008 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - NORTHEAST
2. UPON REACHING TYPHOON INTENSITY - EAST

III. FINAL DISPOSITION

A. DISSIPATED OVER LAND

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 34
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 15
3. DIATANCE TRAVELED DURING WARNING PERIOD - 2226 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 948 MBS AT 192100Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2652M AT 200230Z
3. MAXIMUM SURFACE WIND - 085 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 330 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - 200 MB ANTICYCLONE OVER THE SURFACE CYCLONE

B. INITIAL SURFACE VORTEX

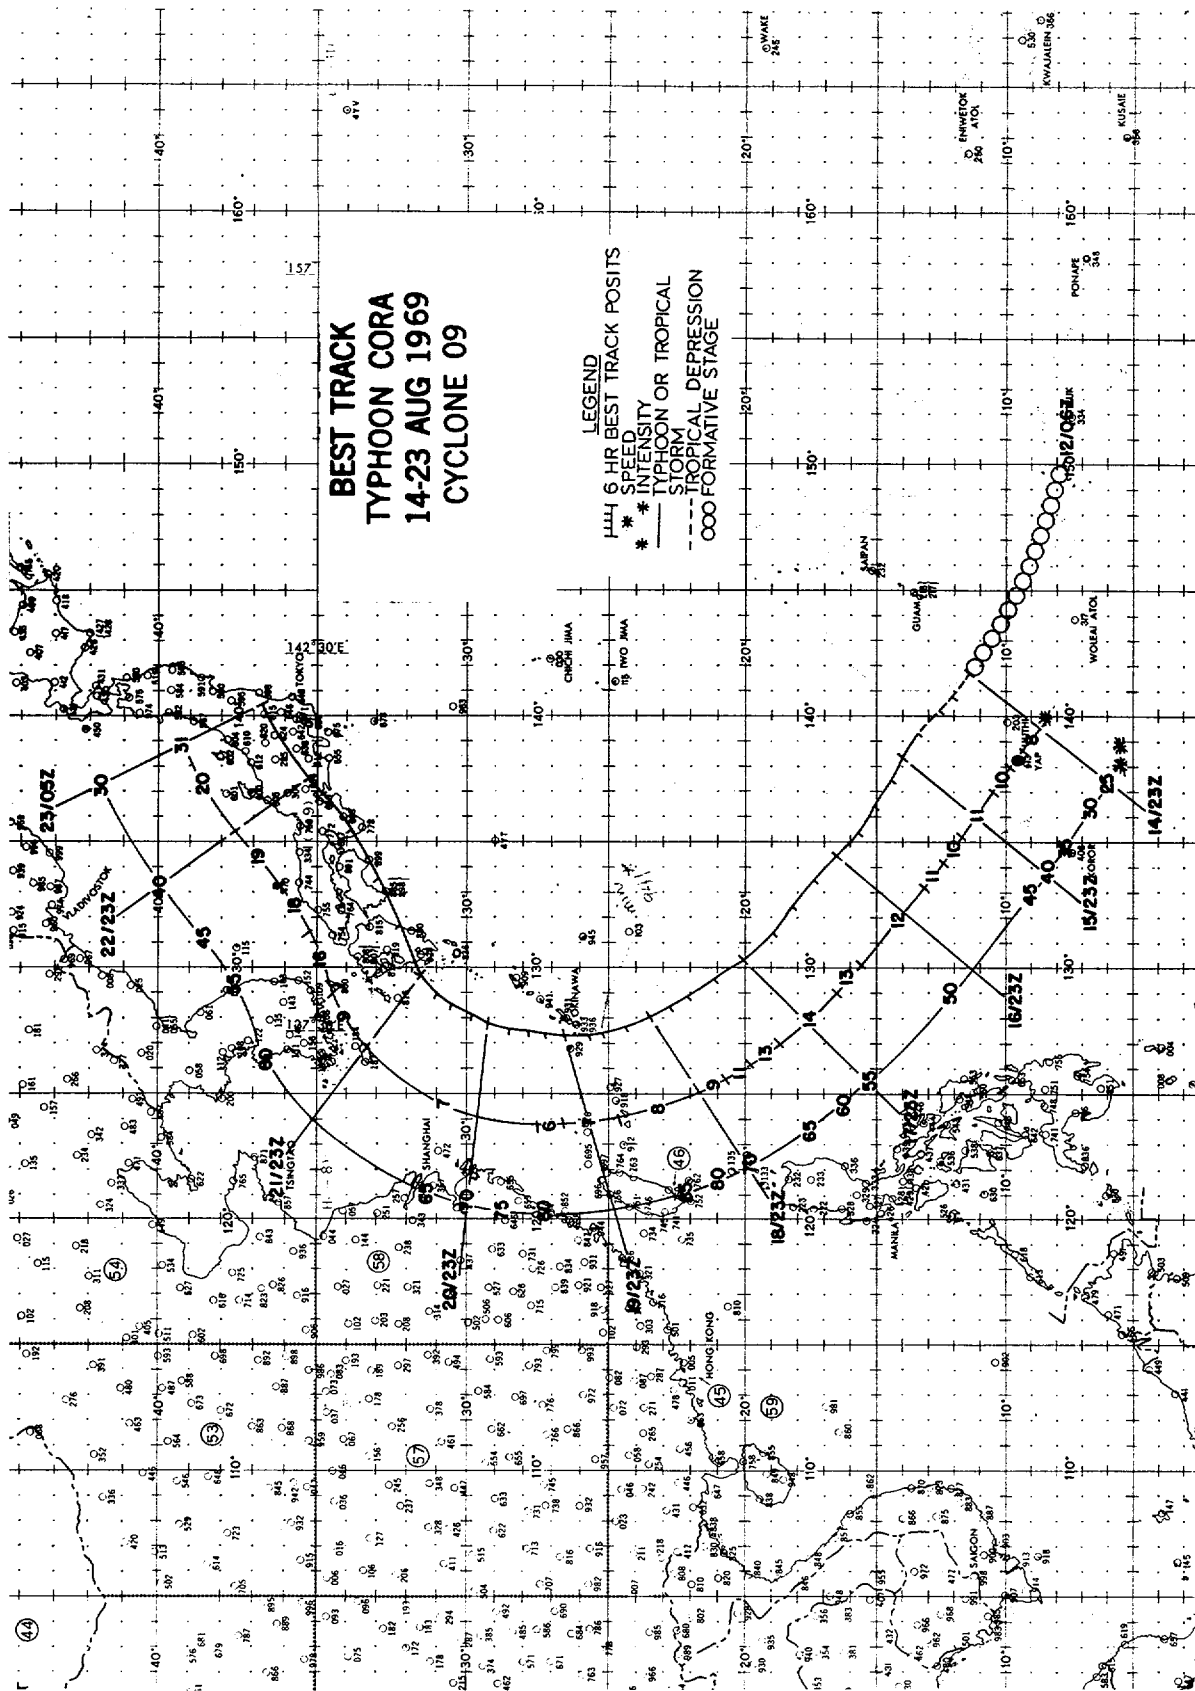

1. JUNCTION VORTEX AT 120600Z
2. SURFACE PRESSURE LESS THAN 1007 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - SOUTHEAST
2. UPON REACHING TYPHOON INTENSITY - SOUTHEAST

III. FINAL DISPOSITION

A. BECAME EXTRATROPICAL

TYPHOON DORIS - 08/31/0500Z TO 09/02/0500Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 09
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 03
3. DISTANCE TRAVELED DURING WARNING PERIOD - 612 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 973 MBS AT 010250Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2865 M AT 010250Z
3. MAXIMUM SURFACE WIND - 065 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 240 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - DEVELOPMENT OF DIVERGENCE AT 200 MB
OVER SURFACE CYCLONIC CIRCULATION

B. INITIAL SURFACE VORTEX

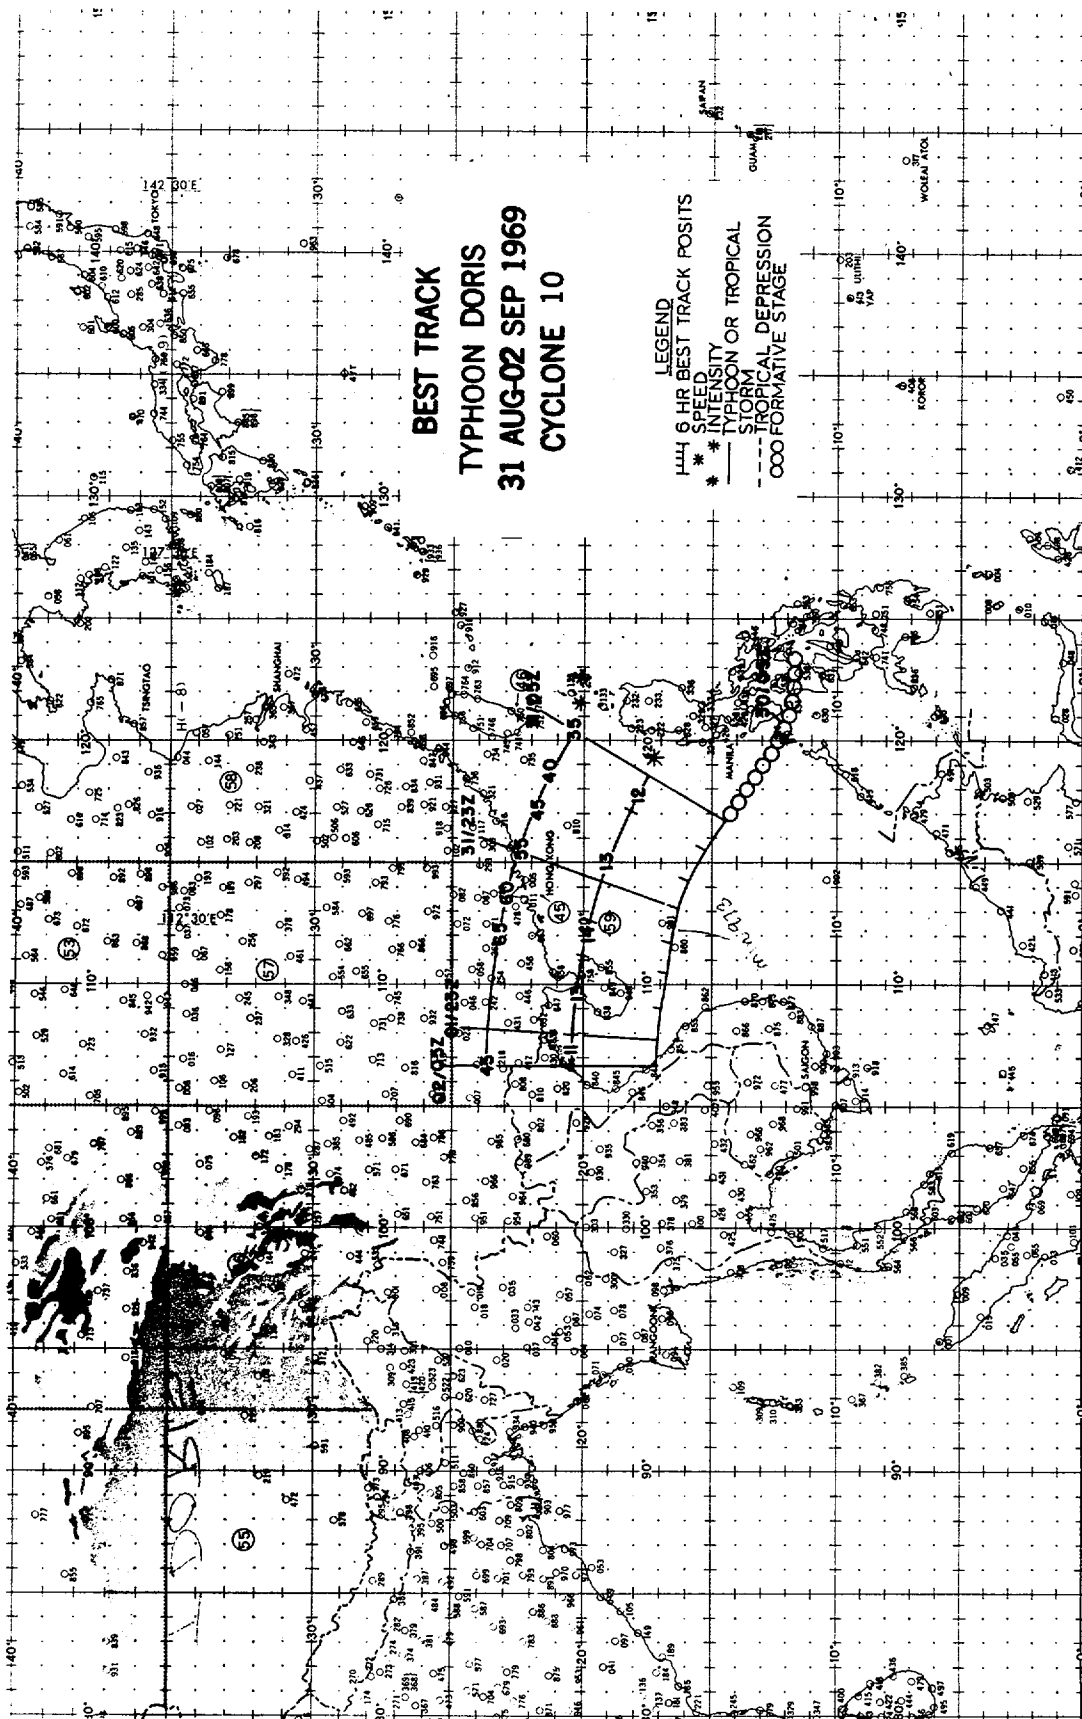

1. INDUCED VORTEX AT 300600Z
2. SURFACE PRESSURE LESS THAN 1006 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - NORTHEAST
2. UPON REACHING TYPHOON INTENSITY - NORTHEAST

AVERAGE 24 HOUR ERROR - 0092 MI.
AVERAGE 48 HOUR ERROR - 0176 MI.
AVERAGE 72 HOUR ERROR - 0316 MI.

TYPHOON GRACE - 09/29/2300Z TO 10/06/2300Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 29
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 21
3. DISTANCE TRAVELED DURING WARNING PERIOD - 2172 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 937 MBS AT 032130Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2548 M AT 032130Z
3. MAXIMUM SURFACE WIND - 095 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 300 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - A COLD CORE LOW BECOMING WARM CORE
AFTER DEVELOPMENT OF DIVERGENCE AT 200 MB

B. INITIAL SURFACE VORTEX

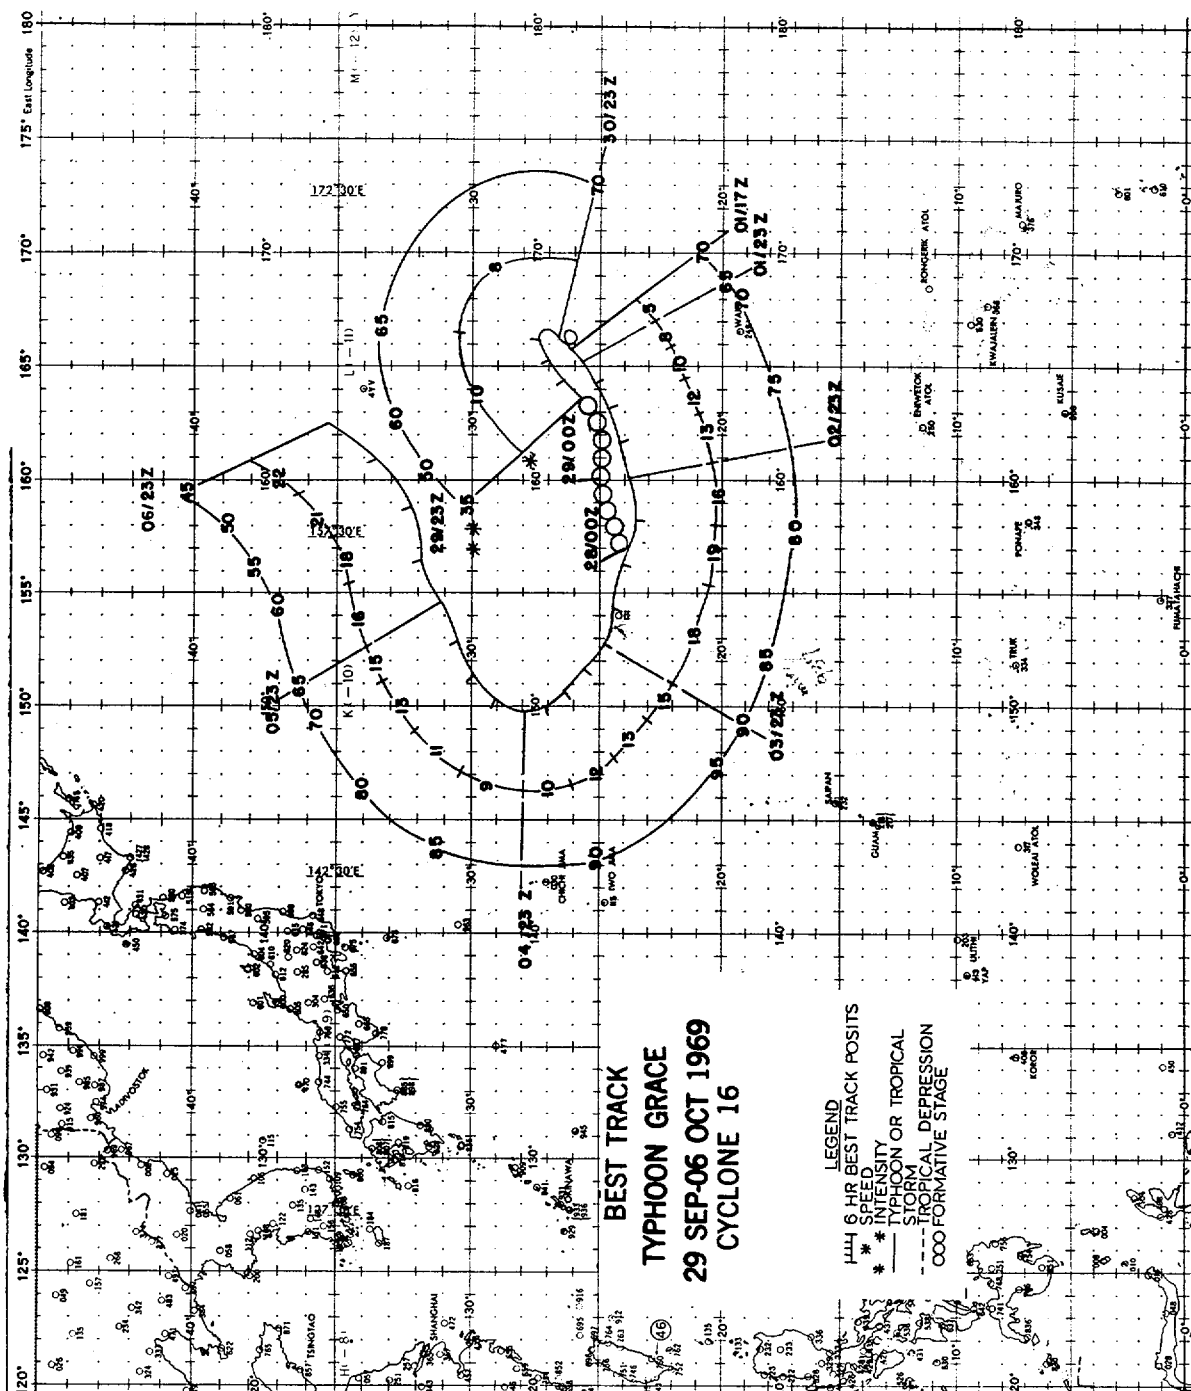

1. COLD VORTEX AT 280000Z
2. SURFACE PRESSURE LESS THAN 1012 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - VARIABLE
2. UPON REACHING TYPHOON INTENSITY - ANTICYCLONIC

III. FINAL DISPOSITION

A. BECAME EXTRATROPICAL

AVERAGE 24 HOUR ERROR - 0186 MI.
AVERAGE 48 HOUR ERROR - 0429 MI.
AVERAGE 72 HOUR ERROR - 0715 MI.

TYPHOON HELEN - 10/08/0500Z TO 10/12/2300Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 20
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 10
3. DISTANCE TRAVELED DURING WARNING PERIOD - 2340 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 930 MBS AT 110300Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2481 M AT 110300Z
3. MAXIMUM SURFACE WIND - 105 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 330 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - 200 MB ANTICYCLONE OVER THE SURFACE CYCLONE

B. INITIAL SURFACE VORTEX

1. JUNCTION VORTEX AT 060600Z
2. SURFACE PRESSURE LESS THAN 1007 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - ANTICYCLONIC
2. UPON REACHING TYPHOON INTENSITY - EAST

III. FINAL DISPOSITION

A. BECAME EXTRATROPICAL

AVERAGE 24 HOUR ERROR - 0123 MI.
AVERAGE 48 HOUR ERROR - 0438 MI.
AVERAGE 72 HOUR ERROR - 0420 MI.

TYPHOON IDA - 10/15/2300Z TO 10/22/0500Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 26
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 17
3. DISTANCE TRAVELED DURING WARNING PERIODS - 1296 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 917 MBS AT 172050Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2384 M AT 172050Z
3. MAXIMUM SURFACE WIND - 115 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 360 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - DEVELOPMENT OF DIVERGENCE AT 200 MB
OVER SURFACE CYCLONIC CIRCULATION

B. INITIAL SURFACE VORTEX

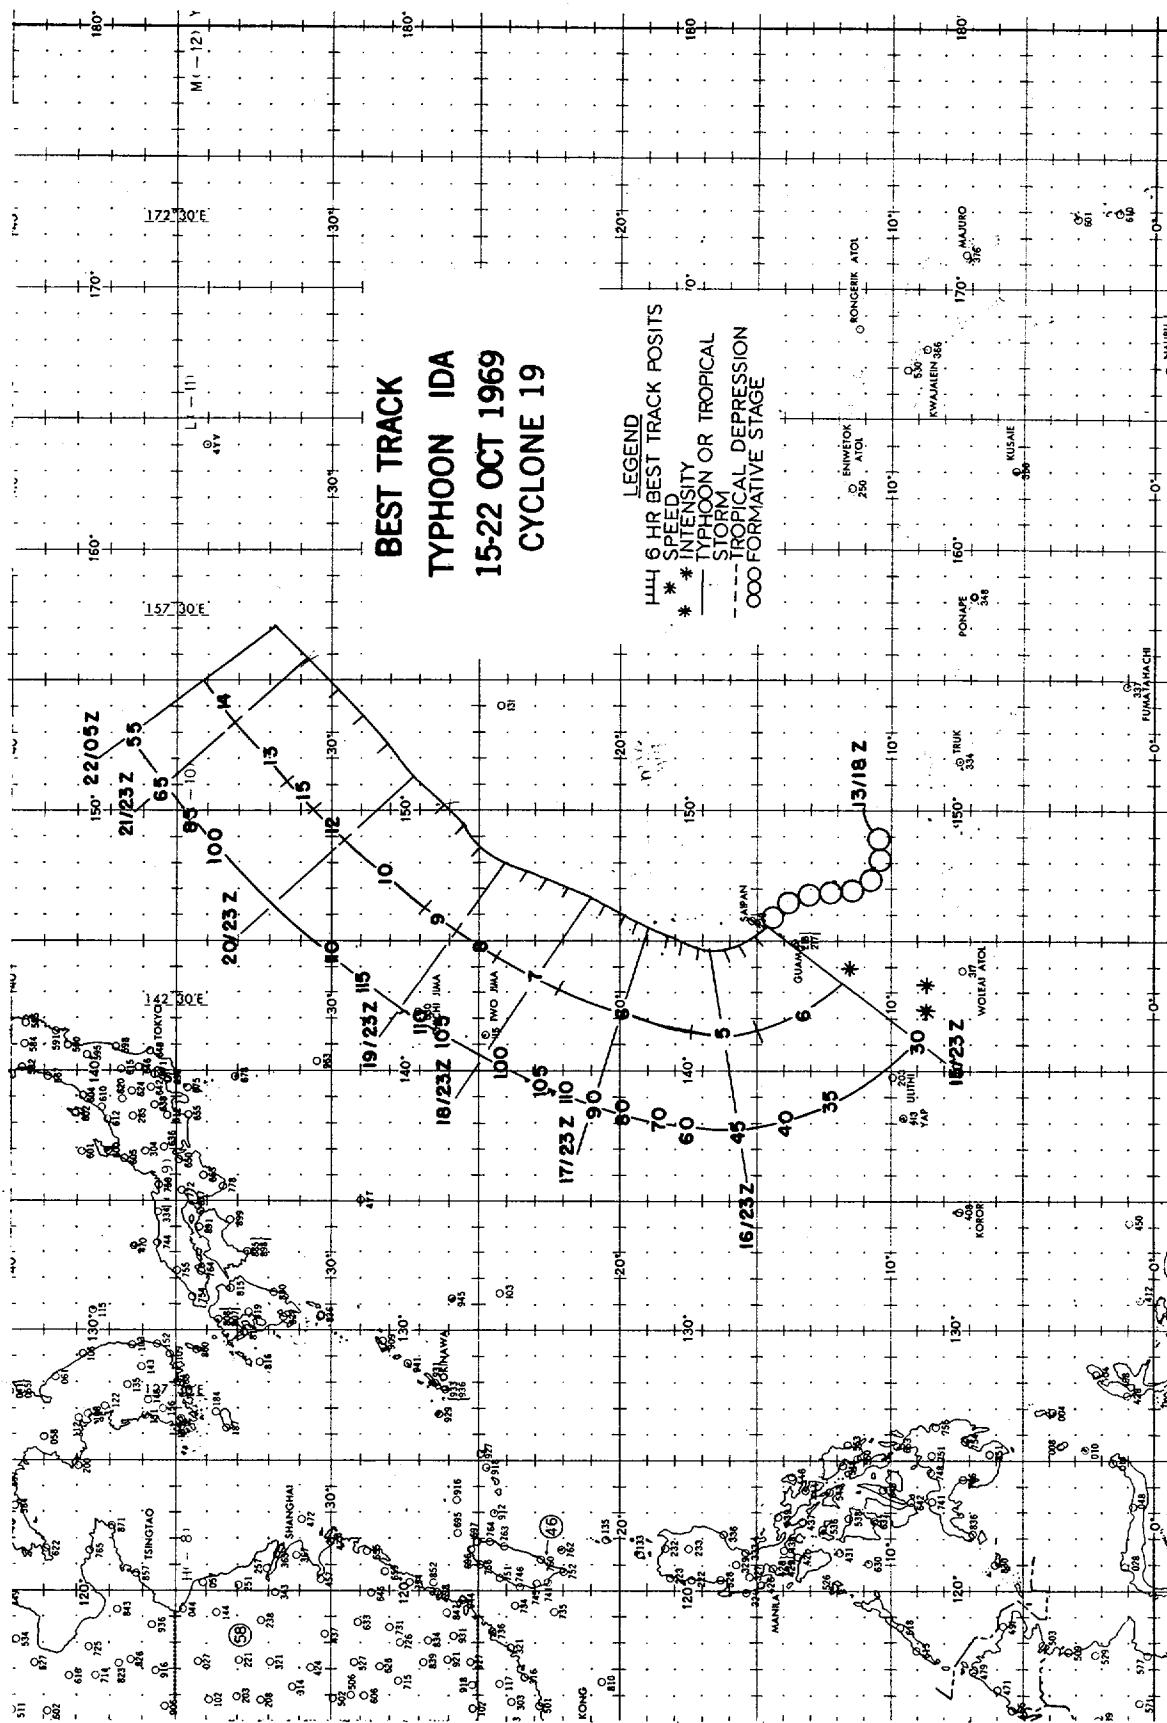

1. JUNCTION VORTEX AT 131800Z
2. SURFACE PRESSURE LESS THAN 1008 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - SOUTHWEST
2. UPON REACHING TYPHOON INTENSITY - SOUTHWEST

III. FINAL DISPOSITION

A. BECAME EXTRATROPICAL

TYPHOON JUNE - 10/28/0500Z TO 11/05/0500Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 33
2. NUMBER OF WARNINGS WITH TYPHOON INTENSITY - 21
3. DISTANCE TRAVELED DURING WARNING PERIOD - 1782 MI

B. CHARACTERISTICS AS A TYPHOON

1. MINIMUM OBSERVED SLP - 936 MBS AT 020820Z
2. MINIMUM OBSERVED 700 MB HEIGHT - 2643 M AT 021420Z
3. MAXIMUM SURFACE WIND - 105 KTS (FROM BEST TRACK)
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 500 MI

II. DEVELOPMENT

A. INITIAL IMPETUS - 200 MB ANTICYCLONE OVER THE SURFACE CYCLONE

B. INITIAL SURFACE VORTEX

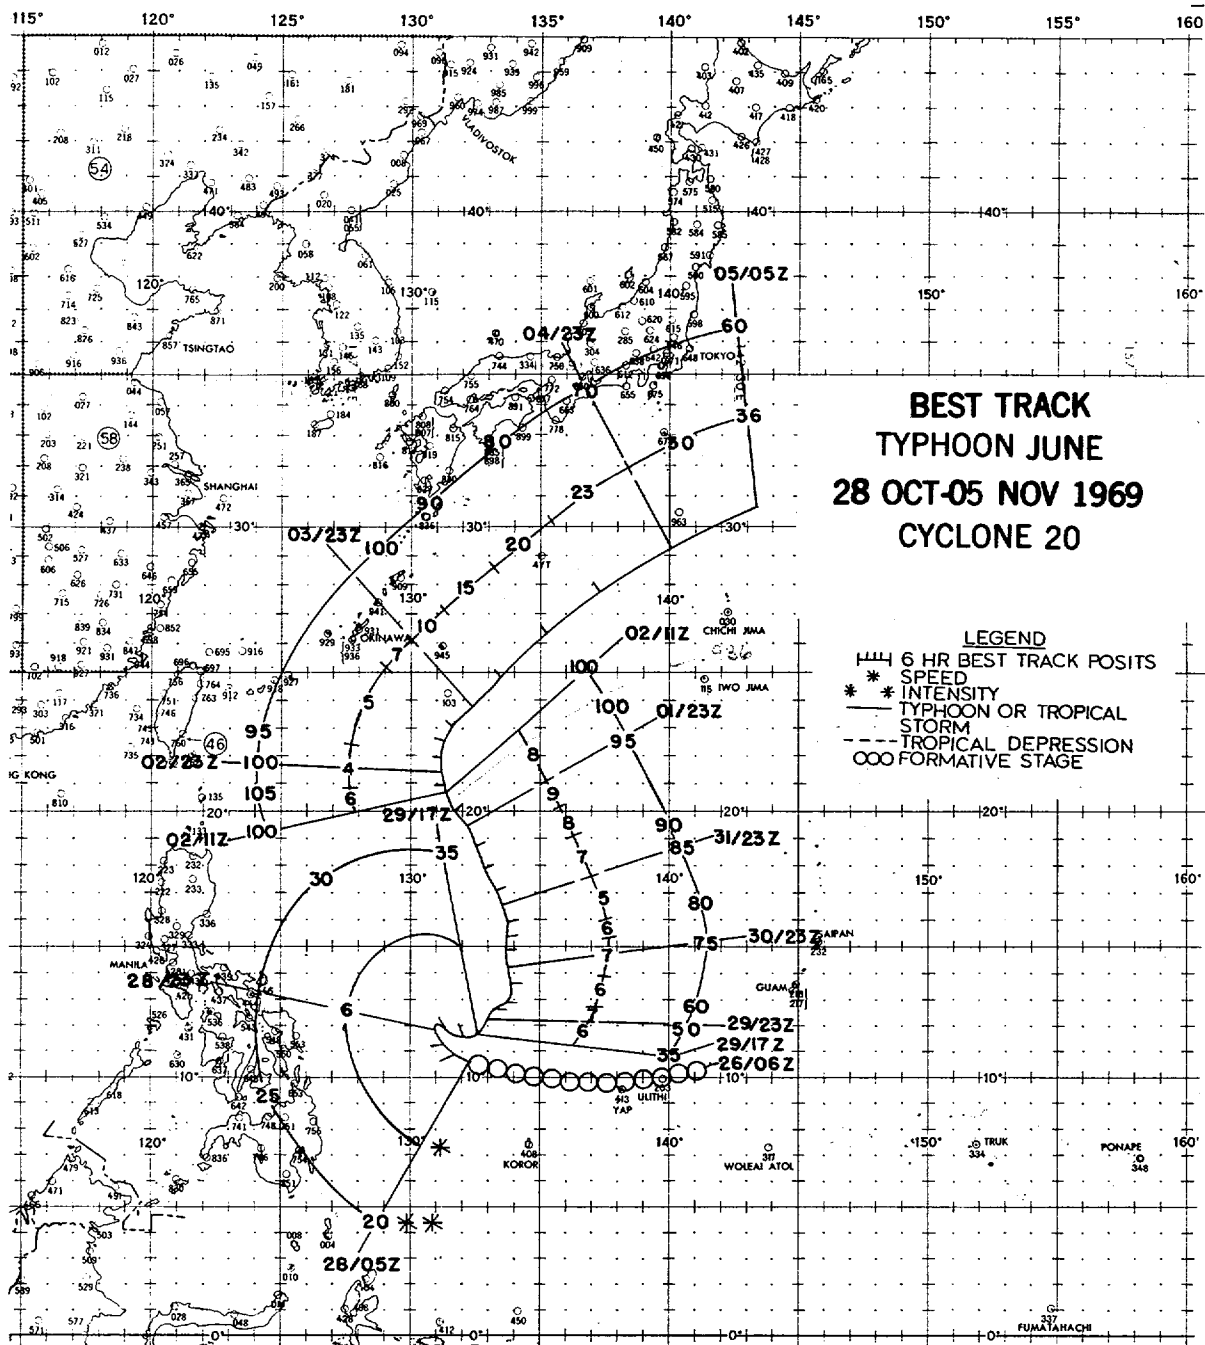

1. JUNCTION VORTEX AT 260600Z
2. SURFACE PRESSURE LESS THAN 1005 MBS

C. 200 MB FLOW ABOVE SURFACE VORTEX

1. INITIAL - SOUTHEAST
2. UPON REACHING TYPHOON INTENSITY - ANTICYCLONIC

III. FINAL DISPOSITION

A. BECAME EXTRATROPICAL

ANNEX

A

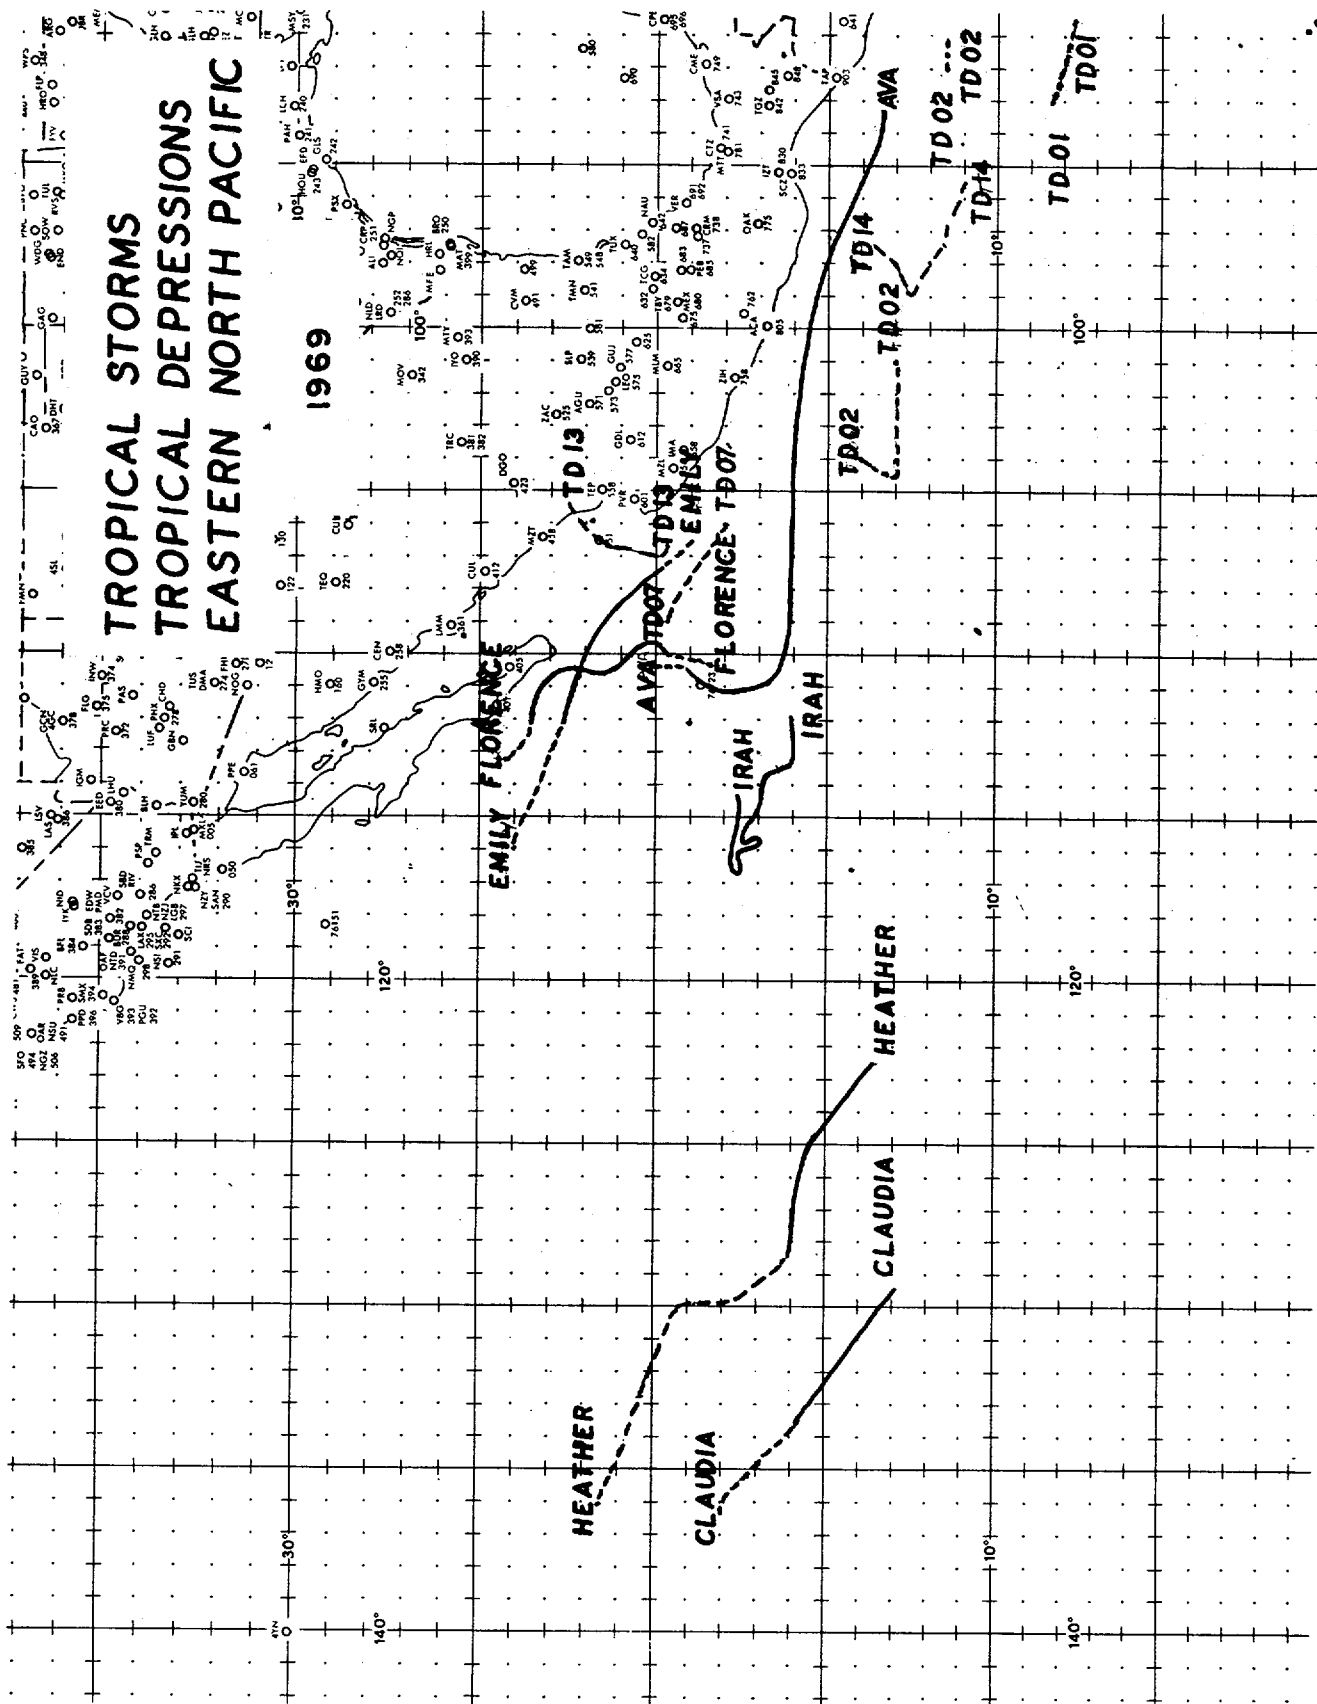

SUMMARY OF TROPICAL CYCLONES

IN THE

EASTERN NORTH PACIFIC OCEAN

FOR

1969

1969

EASTERN NORTH PACIFIC

During the 1969 EastPac Tropical Cyclone season, Fleet Weather Central, Alameda, issued a total of 219 Tropical Warnings on four hurricanes, six tropical storms and five tropical depressions. No tropical cyclones originating in Fleet Weather Central, Alameda's area moved out of the area. The 15 tropical cyclones identified this year is the lowest number since 1965 and the number of warnings was the lowest since 1964, reflecting an unusually inactive season. No specific reasons for this apparent inactivity have been determined.

The following eight year summary covering tropical cyclones originating in Fleet Weather Central, Alameda's area of responsibility is presented for comparison. Included are warnings issued by Fleet Weather Central, Pearl Harbor, when the tropical cyclone originated in the Alameda area.

	<u>1962</u>	<u>1963</u>	<u>1964</u>	<u>1965</u>	<u>1966</u>	<u>1967</u>	<u>1968</u>	<u>1969</u>
Total Number of Warnings*	122	80	60	244	342	474	531	219
Calendar Days of Warnings*	35	26	21	73	70	119	126	67
Tropical Depressions*				2	6	2	6	5
Tropical Storms	6	5	4	9	6	12	13	6
Hurricanes	2	4	2	1	7	6	6	4
Total Tropical Cyclones*	8	9	6	12	19	20	25	15

*Tropical Depression information not available 1962-1964

Jennifer was the only tropical cyclone that caused damage on land. One person was killed, 15 injured and a large ferry and 12 shrimp boats were reported swamped at Mazatlan, Mexico. Thirty other shrimp boats were reported lost in smaller harbors nearby. There was extensive property damage along a 100 mile section of the coast but information on money amounts and specific losses are not available. The highest reported winds at Mazatlan Airport were 50 knots with gusts to 70 at 2100Z, 11 October.

Forecasting tools used included twice daily readouts of the Fleet Numerical Weather Central's "HATRACK" steering program, extrapolation and subjective reasoning. While a definitive study of the various techniques has not been made, the latter two methods, coordinated with the Hurricane Warning Office, ESSA Weather Bureau, San Francisco, appear to be the most successful.

This season marked the inauguration of U. S. Navy responsibility in the Eastern Pacific for tropical cyclone reconnaissance. Efforts were limited by resources (two EC-131 aircraft and two meteorological crews operating from the Pacific Missile Range, Pt. Mugu, California) and no routinely available staging points from which to base aircraft to cover distant storms (more than 1200 nautical miles from Pt. Mugu). Early in the season Acapulco, Mexico was used but 48 hours advance notification was required. Later in the season, limited funds precluded the use of Acapulco except in an emergency. Because of the aircraft configuration (EC-121 vice WC-121), penetrations could not be made and low level eye data was not available. The USAF continued to fly tropical cyclone reconnaissance missions in addition to scheduled Navy flights. High level reconnaissance data are available from that source.

Limited resources, coupled with the great distance at which most of the tropical cyclones were found caused APT data to remain as in previous years, the primary source of fixes. Insufficient reconnaissance data were available to make any meaningful verification of tropical cyclone intensity estimates based on satellite pictures.

TROPICAL CYCLONES FOR THE 1969 SEASON

ORIGINATED BY FLEET WEATHER CENTRAL, ALAMEDA

	<u>CYCLONE</u>	<u>PERIOD</u>
01	Tropical Depression 01	31 May 1969
02	Tropical Depression 02	04 June-05 June 1969
	REGENERATED	07 June-08 June 1969
03	Tropical Storm AVA	02 July-07 July 1969
04	Hurricane BERNICE	08 July-17 July 1969
05	Tropical Storm CLAUDIA	21 July-23 July 1969
06	Hurricane DOREEN	04 August-09 August 1969
07	Tropical Depression 07	09 August 1969
08	Tropical Storm EMILY	22 August-24 August 1969
09	Tropical Storm FLORENCE	02 September-07 September 1969
10	Hurricane GLENDA	08 September-12 September 1969
11	Tropical Storm HEATHER	18 September-22 September 1969
	REGENERATED	23 September-25 September 1969
12	Tropical Storm IRAH	30 September-03 October 1969
13	Tropical Depression 13	03 October-04 October 1969
14	Tropical Depression 14	03 October-05 October 1969
15	Hurricane JENNIFER	08 October-12 October 1969

Below is a summary of aircraft fixes made on hurricanes and tropical storms during the 1969 season.

<u>CYCLONE</u>	<u>DATE/TIME REQ.</u>	<u>DATE/TIME FIX</u>	<u>REMARKS</u>
DOREEN 4-9 Aug	061800Z 071800Z 081800Z	061730Z 071800Z 081905Z	USAF FIX ALSO AT 071800Z 071800Z
EMILY 22-24 Aug	240000Z	232300Z	USAF FIX ALSO AT 231840Z
FLORENCE 2-7 Sep	031800Z 050000Z 060000Z 080000Z	031755Z 042340Z 052315Z CANCELED	USAF FIX ALSO AT 041824Z USAF FIX ALSO AT 951732Z USAF FIX AT 061805Z. NAVY RECON CANCELED DUE STORM DISSIPATION
GLENDIA 8-12 Sep	091800Z 110000Z 120000Z	091800Z 110000Z 120030Z	USAF FIX ALSO AT 091748Z USAF FIX ALSO AT 101730Z USAF FIX ALSO AT 111713Z
HEATHER 18-25 Sep	NO NAVY RECON REQUESTED		USAF FIX AT 201825Z USAF FIX AT 211809Z
IRAH 30 Sep- 3 Oct	011800Z 030000Z	011900Z NO FIX	USAF FIX ALSO AT 011800Z ACFT FLEW BUT UNABLE TO LOCATE DISCERNABLE CENTER
JENNIFER 8-12 Oct	110000Z 120000Z	NO FIX CANCELED	ACFT NOT AVAIL FOR RECON FLIGHT. USAF FIXED AT 091800Z AND 101740Z STORM DISSIPATED. USAF FIX AT 111800Z

A total of 15 requests for Navy reconnaissance were made and two were subsequently canceled. Of the 13 remaining requests, only one could not be met and that was due to non-availability of aircraft. Twelve Navy reconnaissance flights were made. During the same period the U.S. Air Force 9th Weather Reconnaissance Wing flew 14 missions.

24 HOUR FORECAST ERROR = 100.4 MILES
48 HOUR FORECAST ERROR = 200.6 MILES
72 HOUR FORECAST ERROR = 251.3 MILES

HURRICANE GLENDA - 09/08/0000Z to 09/12/0600Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 18
2. NUMBER OF WARNINGS WITH HURRICANE INTENSITY 1
3. DISTANCE TRAVELED DURING WARNING PERIOD - 1248 MILES

B. CHARACTERISTICS

1. MINIMUM OBSERVED SEA LEVEL PRESSURE - UNKNOWN
2. MINIMUM OBSERVED 700 MB HEIGHT - UNKNOWN
3. MAXIMUM SURFACE WIND - 65 KT
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 125 MILES

II. DEVELOPMENT

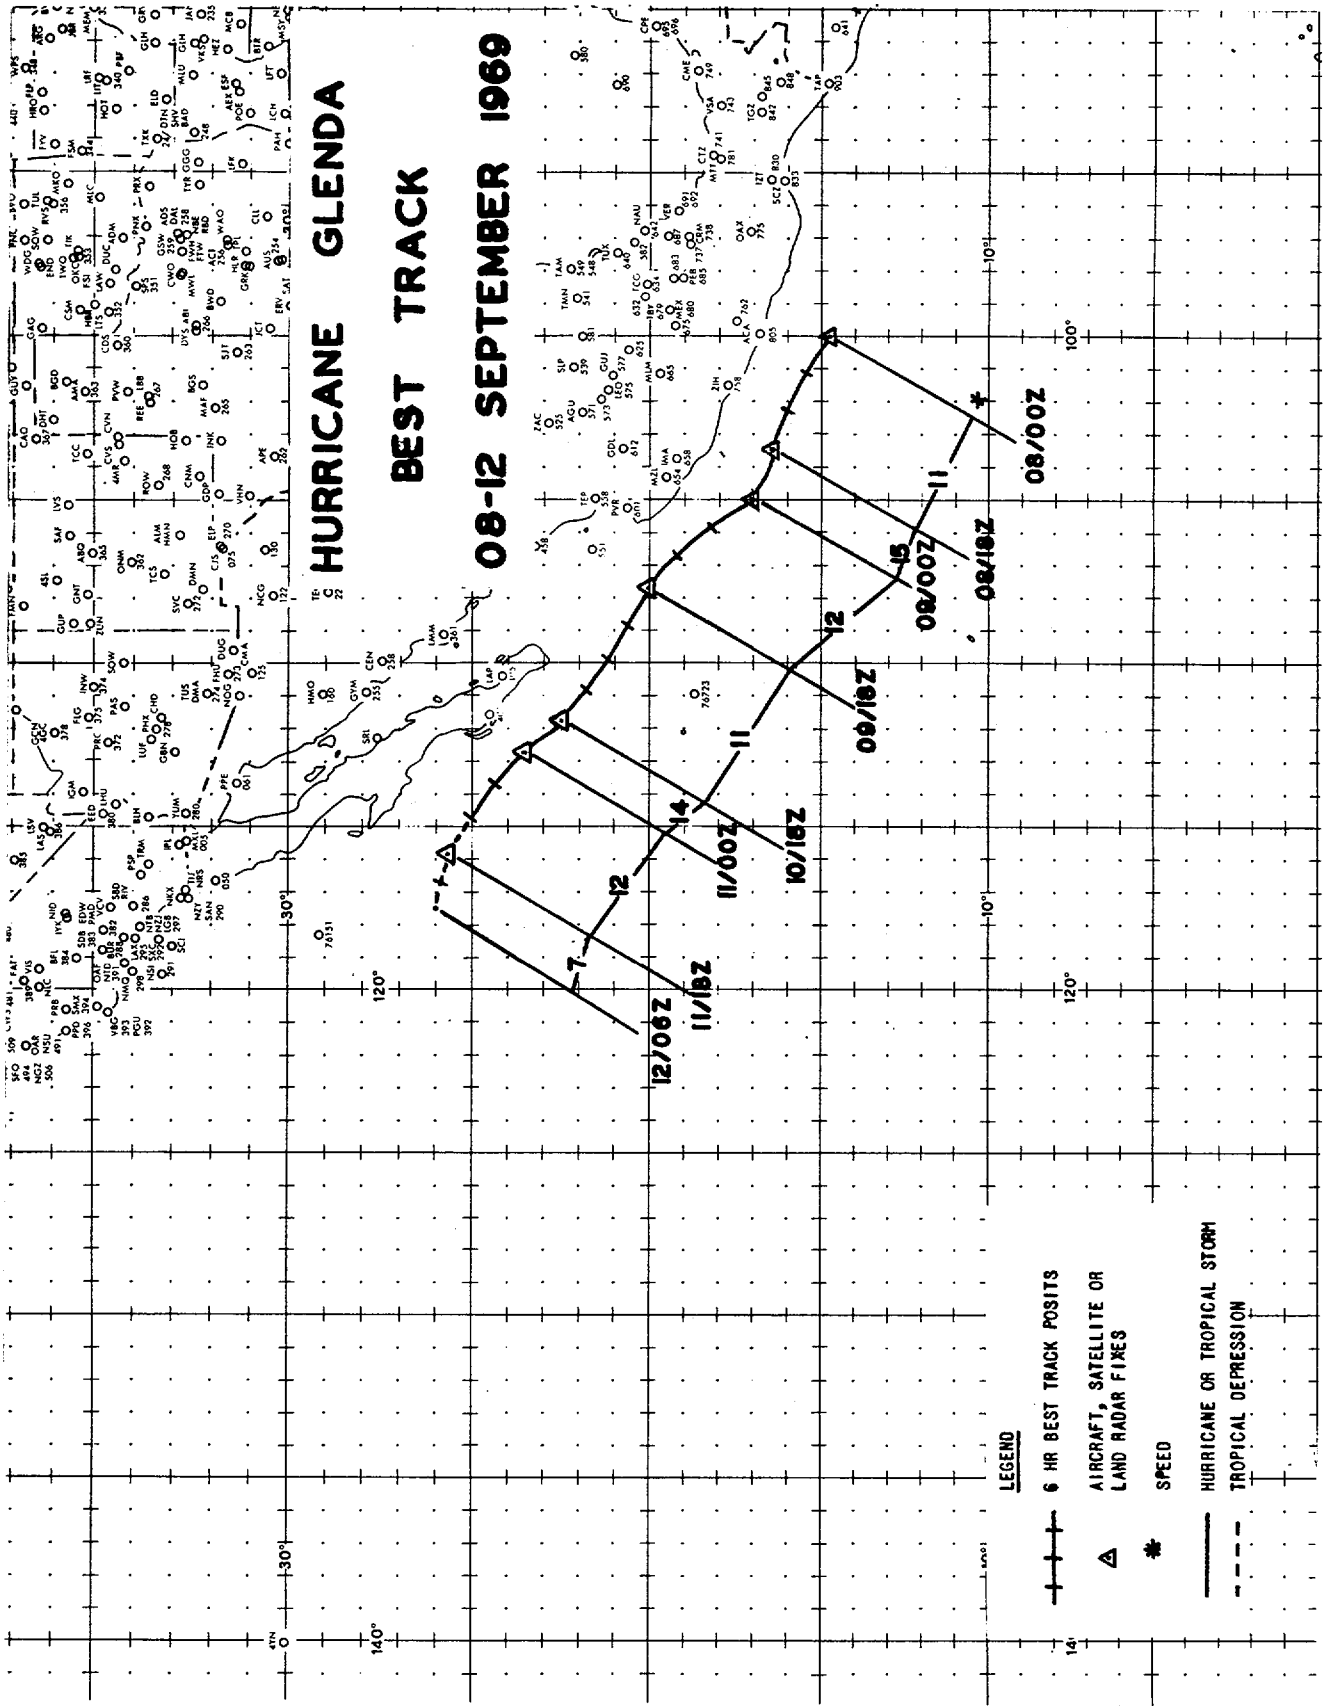

A. INITIAL IMPETUS - ITCZ

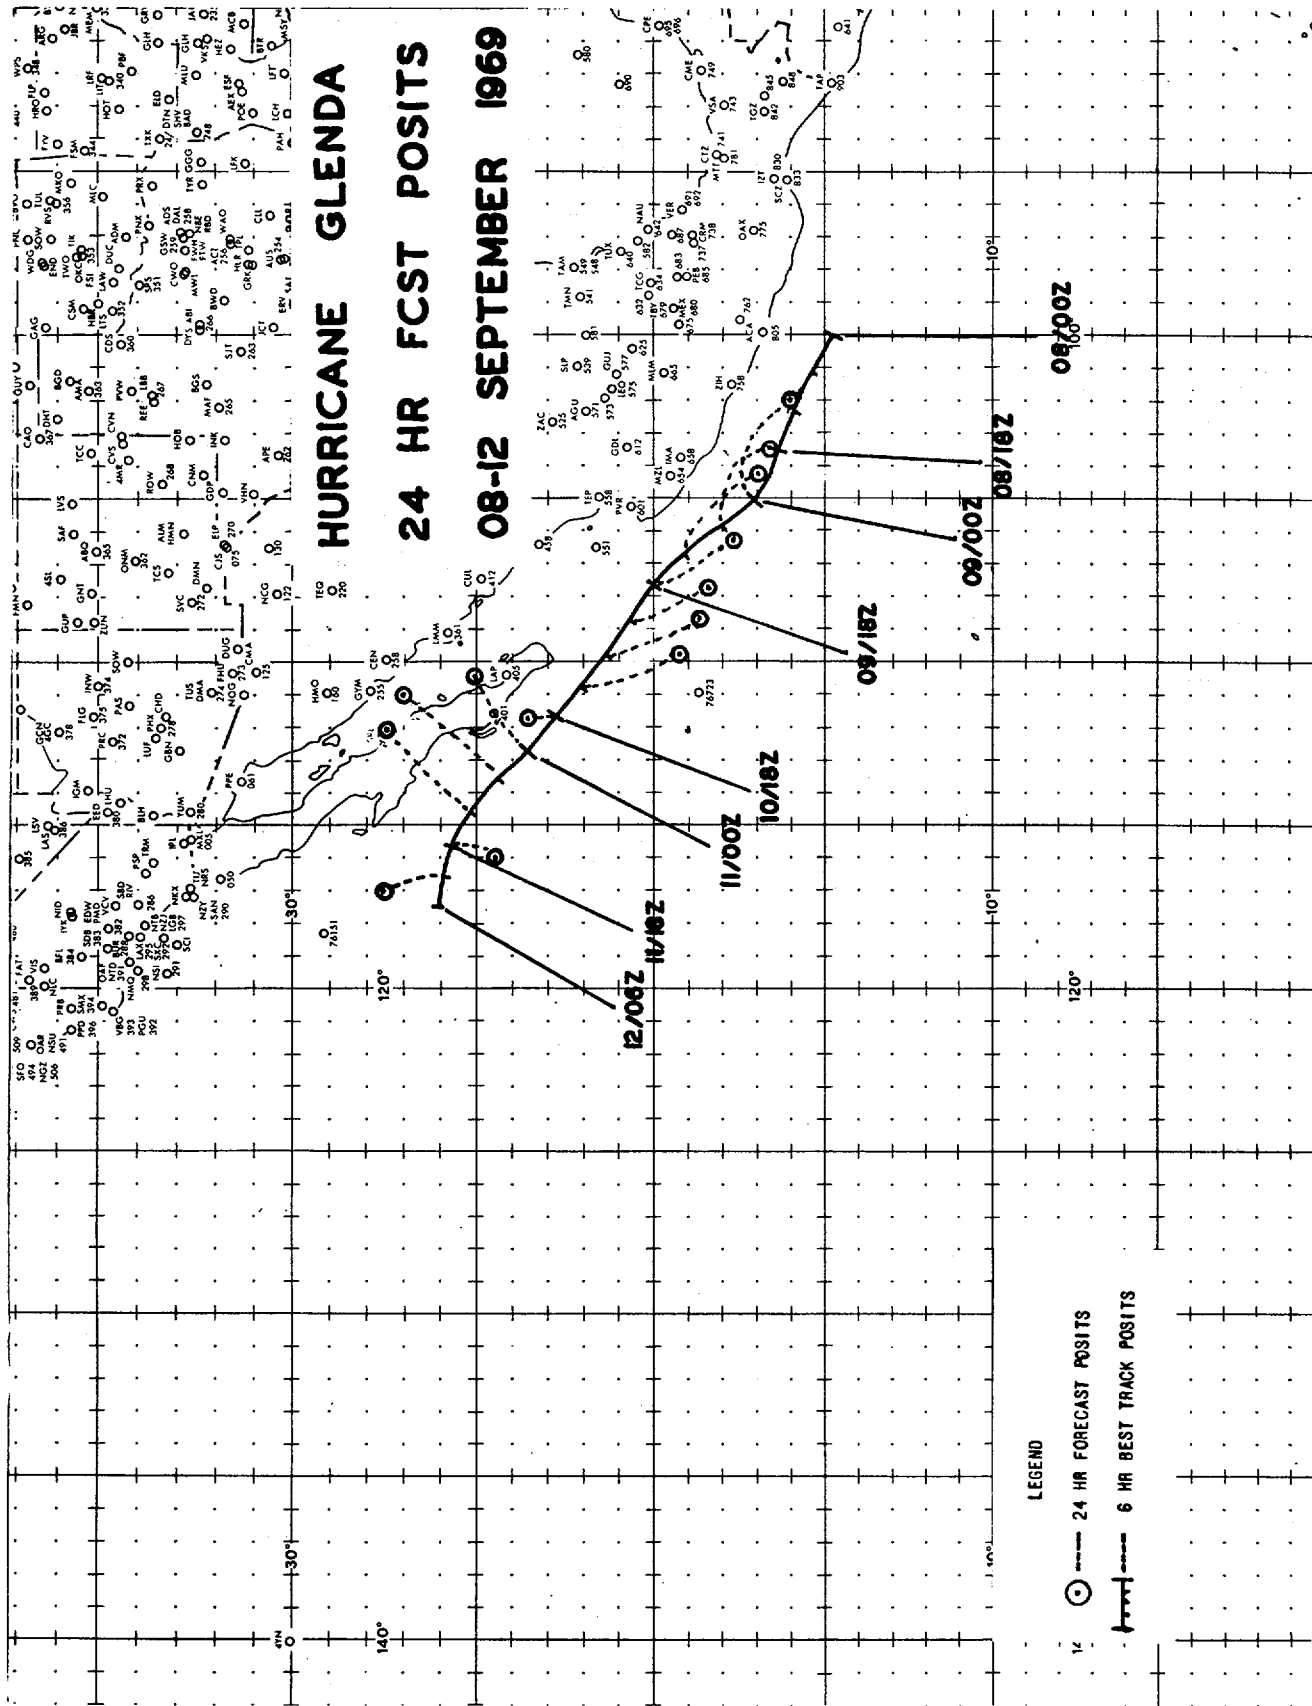

B. INITIAL SURFACE VORTEX

1. 080000Z
2. SURFACE PRESSURE LESS THAN 1008 MB

III. FINAL DISPOSITION

A. DISSIPATED OVER WATER

HURRICANE JENNIFER - 11/08/1800Z TO 11/12/0300Z

I. DATA

A. STATISTICS

1. NUMBER OF WARNINGS ISSUED - 15
2. NUMBER OF WARNINGS WITH HURRICANE INTENSITY - 8
3. DISTANCE TRAVELED DURING WARNING PERIOD - 754 NM

B. CHARACTERISTICS

1. MINIMUM OBSERVED SEA LEVEL PRESSURE - N/A
2. MINIMUM OBSERVED 700 MB HEIGHT - N/A
3. MAXIMUM SURFACE WIND - 70 KTS
4. MAXIMUM RADIUS OF SURFACE CIRCULATION - 65 NM

II. DEVELOPMENT

A. INITIAL IMPETUS - ITCZ

B. INITIAL SURFACE VORTEX

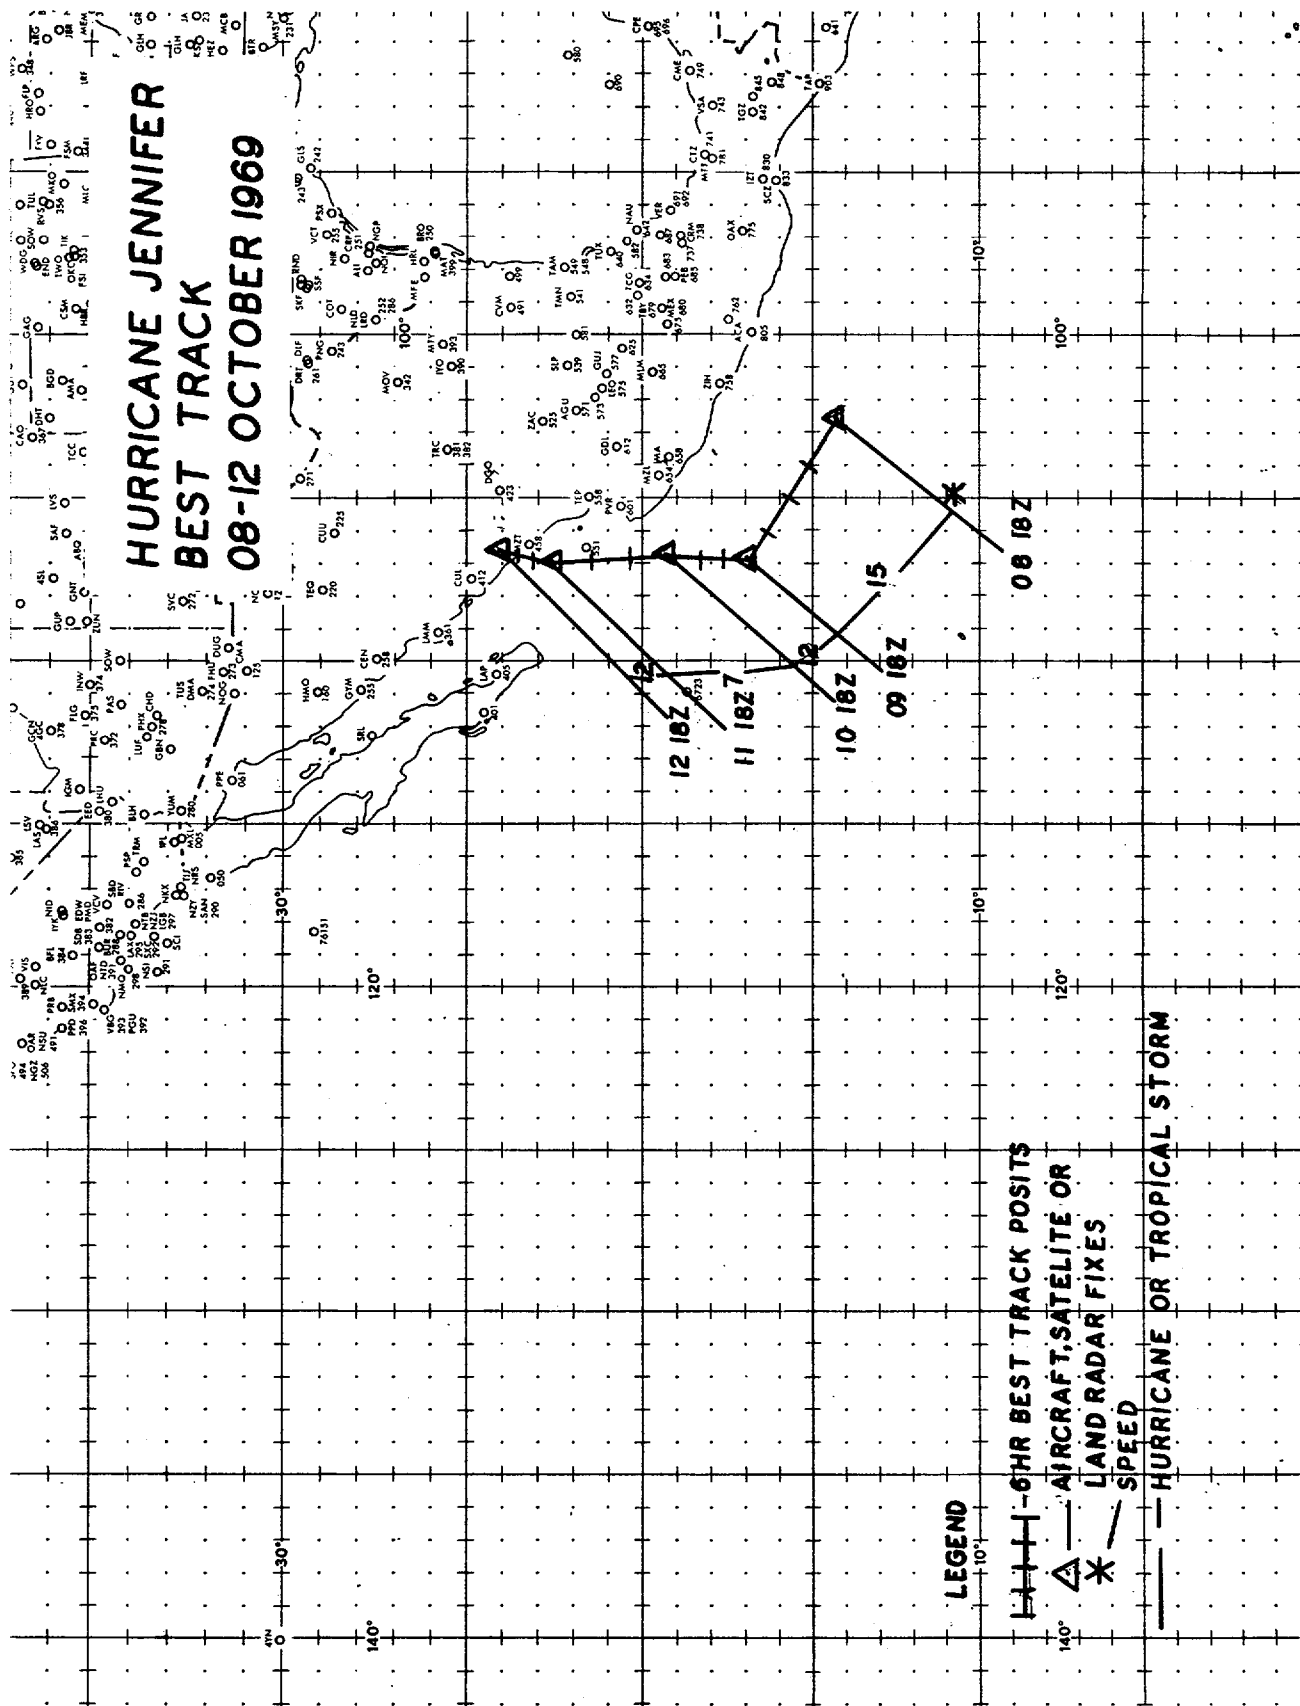

1. 08/1800Z
2. SURFACE PRESSURE LESS THAN 1008 MB

C. TIME STORM REACHED HURRICANE INTENSITY - 09/1800Z

III. FINAL DISPOSITION

A. DISSIPATED OVER LAND.

48 HOUR FORECAST ERROR = 353 MILES
72 HOUR FORECAST ERROR = 509 MILES

APPENDIX A

ABBREVIATIONS AND DEFINITIONS

1. Words and phrases that appear frequently in this report are abbreviated as follows:

ANAL	Analysis
APT	Automatic Picture Transmission
ATS	Applications Technology Satellite
CINCPAC	Commander in Chief, Pacific
CINCPACAF	Commander in Chief, Pacific Air Force
CINCPACFLT	Commander in Chief, Pacific Fleet
CIRC	Circulation
CPA	Closest Point of Approach
DEG	Degree(s)
DTG	Date-Time Group
ESSA	Environmental Science Services Administration
FNWC	Fleet Numerical Weather Central, Monterey, California
FWC/JTWC	Fleet Weather Central/Joint Typhoon Warning Center, Guam
ITCZ or ITC	Intertropical Convergence Zone
JHWC	Joint Hurricane Warning Center, Hawaii
KT(S)	Knot(s)
MAX	Maximum
MB(S)	Millibar(s)
MIN	Minimum
MI or N.M.	Nautical Miles
MOD	Modification
NEDN	Naval Environmental Data Network
NESC	National Environmental Satellite Center, Suitland, Maryland
POSIT(S)	Position(s)
PROG	Prognosis
RECON	Reconnaissance
SLP	Sea Level Pressure
T.	Typhoon
T. D.	Tropical Depression
T. S.	Tropical Storm
VW1	Airborne Early Warning Squadron ONE
54WRS	54th Weather Reconnaissance Squadron

2. The following items define and clarify certain words and phrases that appear in the Eye Fix Summaries in Chapter V. Several definitions in this section have special meanings with regard to the machine prepared Eye Fix Summaries and may not necessarily have the same meaning as used elsewhere in the report.

a. FIX NO. - the chronological order of fixes for each individual tropical cyclone.

b. TIME - the date-time of the fix.

c. POSIT - the latitude and longitude of the fix.

d. UNIT - METHOD - ACCY:

(1) UNIT - the unit that made the fix if made by a reconnaissance squadron; 54-54WRS, VW-VW1.

(2) METHOD - the method used to make the fix; P - penetration, R - radar (these two refer to fixes by reconnaissance squadrons), LND RDR - land radar, SHP RDR - ship radar, SLTIS - satellite cloud picture location.

(3) ACCY - center determination and estimated navigational accuracy of the fix (in nautical miles).

e. FLT LVL - altitude of aircraft at time of fix in whole meters above mean sea level or given as a constant pressure surface; or, stage (STG) of development for a satellite location.

f. FLT LVL WND - maximum observed flight level wind speed in knots; or, diameter (DIA) in whole degrees of latitude for a satellite location.

g. OBS SFC WND - maximum observed surface wind speed in knots; or, number of bands (BNDS) for a satellite location.

h. OBS MIN SLP - minimum observed sea level pressure in whole millibars (reported on penetration fixes only).

i. MIN 700 MB HGT - minimum observed 700 mb level height in whole meters.

j. FLT LVL TT/TD - flight level temperature (TT) and dewpoint (TD) at fix location.

k. EYE FORM - description of cloud eye; CIRC - circular, ELIP - elliptical.

l. ORIENTATION - direction of orientation of an elliptical eye to an eight point compass.

m. EYE DIA - eye diameter or major/minor axes of an elliptical eye, in N. M.

n. THKNS WALL CLOUD - thickness of wall cloud in N. M. if observed. F. B. (feeder bands) or N. F. B. (no feeder bands) may be entered if wall cloud thickness not observed.

3. The following definitions are given to clarify usage in this report:

a. VORTICES:

(1) Cold vortex - a closed cyclonic circulation identified as having originated as a cold core system removed from the ITCZ or any easterly wave.

(2) Embedded vortex - a closed cyclonic circulation along an easterly wave and separated from the ITCZ.

(3) Junction vortex - a closed cyclonic circulation at the junction of an easterly wave and the ITCZ.

b. RECONNAISSANCE FLIGHTS:

(1) Synoptic track - a set reconnaissance pattern between specified coordinates scheduled to gather and report Meteorological data.

(2) Investigative flight - weather reconnaissance of an area containing a suspected circulation.

(3) Fix mission - aircraft reconnaissance scheduled to fix the center position of and gather peripheral data about a known tropical cyclone.

c. FIX - the determination of the position of a tropical cyclone at a precise time, generally by reconnaissance aircraft penetration of the center or by airborne, land, or ship radar. In the case of a reconnaissance aircraft penetration the actual fix may be based on any of the following: visual observation of the cloud pattern and sea surface, radar, surface pressure, surface or flight level winds, constant pressure height or temperature.

d. The term "tropical cyclone" has two definitions as used herein depending on usage:

(1) "Tropical cyclone" may be used to describe a suspect cyclonic circulation which appears to be capable of intensification.

(2) "Tropical cyclone" may be used in the general sense e.g., "Typhoon Agnes was the most intense tropical cyclone of 1968", or "tropical cyclones most frequently develop during August and September".

e. TROPICAL DEPRESSION (T.D.) - as used by JTWC this is a numbered tropical cyclone in which the maximum sustained surface wind speed is 33 knots or less and whose winds are expected to increase to 34 knots or more within 48 hours.

f. TROPICAL STORM (T.S.) - a named tropical cyclone in which the maximum sustained surface wind speed is greater than 33 knots but less than 64 knots.

g. TYPHOON/HURRICANE - a named tropical cyclone in which the maximum sustained surface wind speeds are 64 knots or greater. West of 180 degrees longitude these are called typhoons, east of

180 degrees they are called hurricanes. All references to typhoons apply equally to hurricanes.

h. Recurvature - that point at which a tropical cyclone ceases movement to the west of north and commences moving east of north.
